

# Neutrino experimental search in ICARUS

A. Guglielmi  
INFN/Padova

- neutrinos ?!
- ICARUS LAr-TPC
- Sterile neutrino search @ PS

- Neutrino oscillation have established a coherent picture with number of experimental hints consistent with the mixing of 3 physical neutrinos  $\nu_e, \nu_\mu$  and  $\nu_\tau$  with mass eigenstates  $\nu_1, \nu_2$  and  $\nu_3$ . In particular the mass differences turn out to be relatively small  $\Delta m^2_{31} \approx 2.4 \times 10^{-3} \text{ eV}^2$  and  $\Delta m^2_{21} \approx 8 \times 10^{-5} \text{ eV}^2$ .
- **Are neutrinos a simple carbon copy repetition of quarks?**  
important discoveries may be ahead:
  - CP violation in the lepton sector : subleading  $\nu_\mu$  to  $\nu_e$  oscillations
  - Sterile neutrinos and others "surprises"
  - Majorana or Dirac neutrinos-  $\beta\beta$  -decay,  $\nu$ -massesNeutrinos have been origin of impressive number of "Surprises"...
- Similar fundamental question: **(barionic) number is forever ?**

# Neutrino oscillations @ accelerators: toward $\Theta_{13}$ , $\delta_{cp}$

- **first generation** long baseline experiments: K2K over 250 km, NuMI and CNGS  $L = 730$  km with conventional  $\nu$  beams, 170 KW.  
Present detectors: SK 22.5 kt W-Cherenkov, MINOS 5.4 kt Iron-Scintillator ICARUS 600 t liquid Argon TPC, OPERA emulsion detector ( $\nu_\tau$  appearance)
- **$\Theta_{13}$ ,  $\delta_{cp}$  measurement in  $\nu_\mu - \nu_e$  subleading oscill. requires major improvements:**
  - high intensity/purity  $\nu$  beams,  $L/E_\nu$  tuned to  $\Delta m_{32}^2$ , well defined spectrum (present beams: intrinsic  $\nu_e$  contamination mainly from  $\mu$  and K decay)
    - $\nu$  Factories: from decay of accelerated muons
    - $\beta$  Beams: from decay of accelerated radioactive ions, just one flavor beam
      - "ultimate" massive detectors, able to measure  $\nu_e$ -CC (i.e. electrons) rejecting  $\nu$ -NC (i.e.  $\pi^0$ ) addressed also to astroparticle physics/p-decay search: 20 -100 kt LAr-TPC (MODULAR, GLACIER), 50 kt L-Scint (LENA), 500 kt W-Cherenkov (MEMPHYS, HyperK)...
- **2<sup>nd</sup> generation** experiments at improved Off-Axis conventional beams, 1 MW power and even beyond: T2K SuperK-detector exposed to 0.7 GeV  $\nu_\mu$  beam, 0.7 MW nominal power,  $L = 295$  km

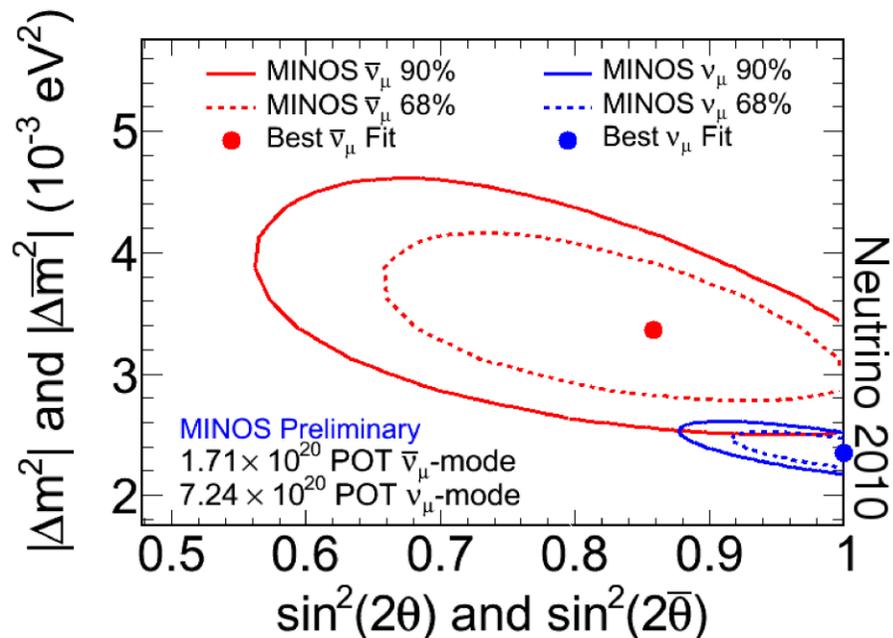

# Are neutrinos a simple carbon copy of quarks?

- However the present picture is not so clean...
- There are a number of "*anomalies*" which, if confirmed experimentally, could be due to the presence of an additional, large squared mass difference in the framework of additional neutrinos with mixing or of other effects.
- If more than the two oscillation signals were to be eventually confirmed, additional Physics beyond the Standard Model in the neutrino sector will be necessary. If a new mass difference  $\Delta m^2_{\text{new}} \geq 1 \text{ eV}^2$  were to be observed, it will also contribute to clarify the Dark Matter problem

# CPT violations ?

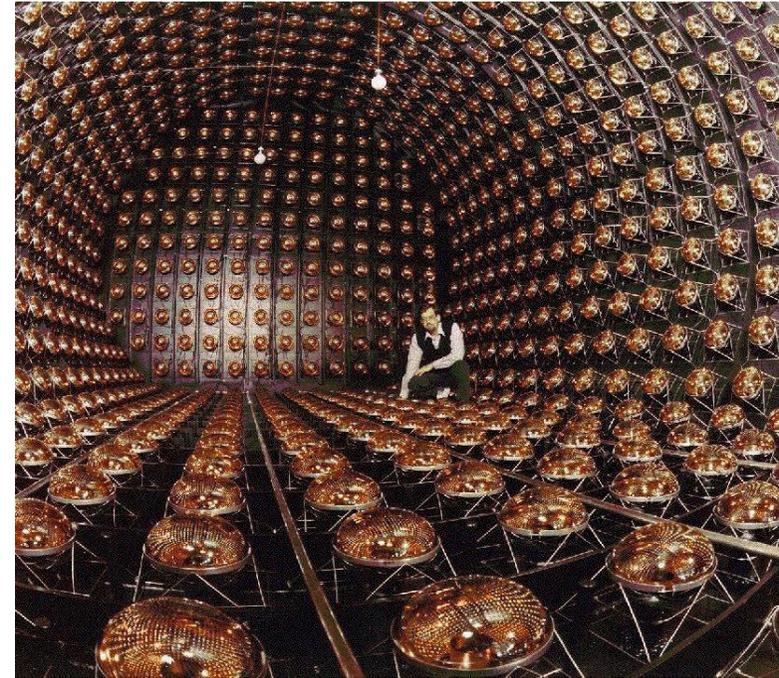

- While reactions and cross sections are different between  $\nu$  and anti- $\nu$ , CPT invariance ensures identity of oscillations.
- The "tension" between the neutrino and antineutrino MiniBooNE + LNSD data seems to indicate a difference of the effective mixing angles in the neutrino and antineutrino channels.
- Such a difference, if confirmed could be due to some unknown mechanism, or perhaps even to CPT violation.

MINOS experiment has recently pointed out a possible difference ( $2\sigma$ ) between the effective mixing  $\nu$  and anti- $\nu$  in the long-baseline channels.

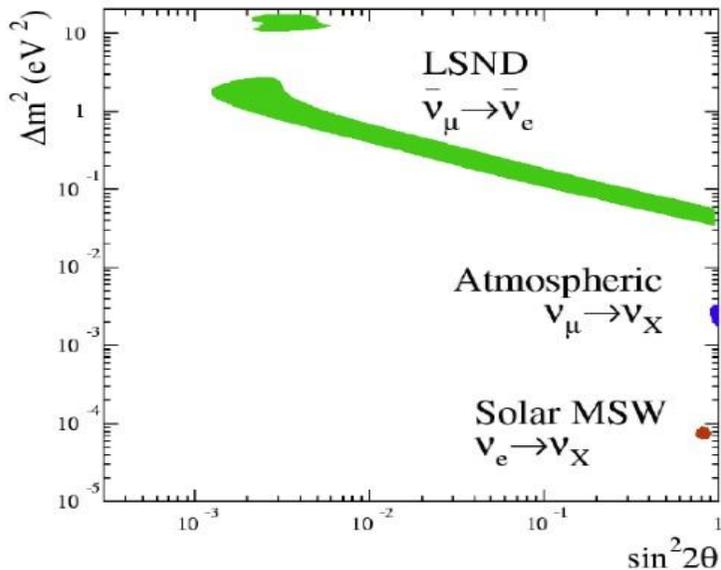

# Additional neutrinos: the LSND Experiment (1993-97)

- LSND observed  $87.9 \pm 22.4 \pm 6.0$  ( $3.8\sigma$ ) excess of anti- $\nu_e$  events in anti- $\nu_\mu$  beam from  $\pi^+$  decay at rest from 800 MeV protons on a Cu/Fe target and an excess of  $\nu_e$  of  $18.1 \pm 6.6 \pm 3.5$  events over backgr. from  $\nu_e C \rightarrow e^- X$
- Since  $\nu_e$  is only  $4 \cdot 10^{-4}$  to  $\nu_{\mu'}$ , it results evidence for  $\nu_\mu \rightarrow \nu_e$  oscillations in  $0.2 < \Delta m^2 < 2.0 \text{ eV}^2$  with probability  $(0.31 \pm 0.12 \pm 0.05)\%$  (anti- $\nu_e$ ) and  $(0.26 \pm 0.10 \pm 0.05)\%$  for  $\nu_e$ .

*Cylindrical tank at 30 m from the neutrino source, filled with 167 tons of liquid scintillator (both Cerenkov and scintillation light detection)*

$$P_{osc} = \sin^2 2\theta \sin^2(1.27 \Delta m^2 L/E)$$

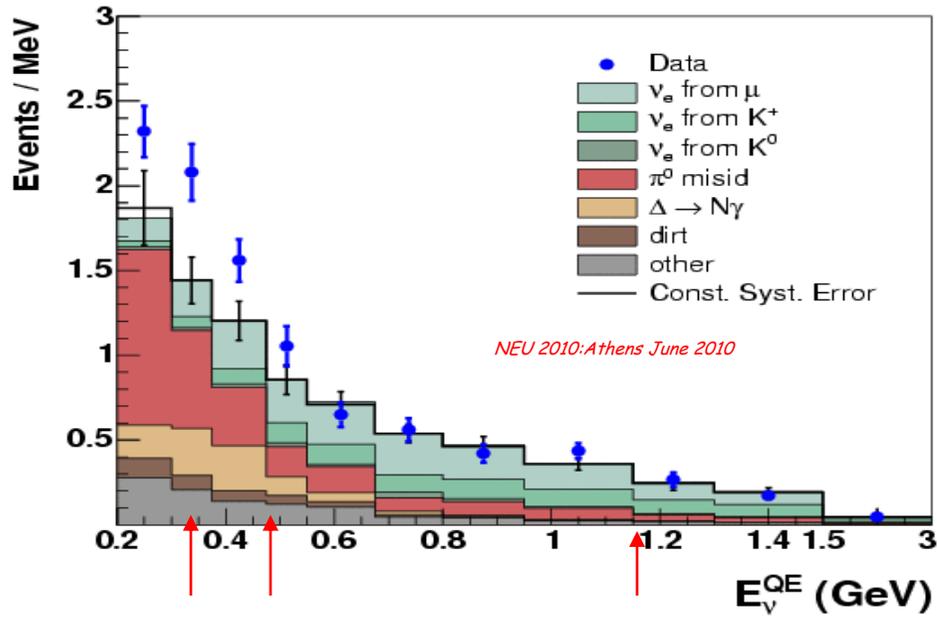

**3 oscillation signals, if confirmed, require new physics beyond SM !**

Baryon Number	Still viable
CPT	Still viable

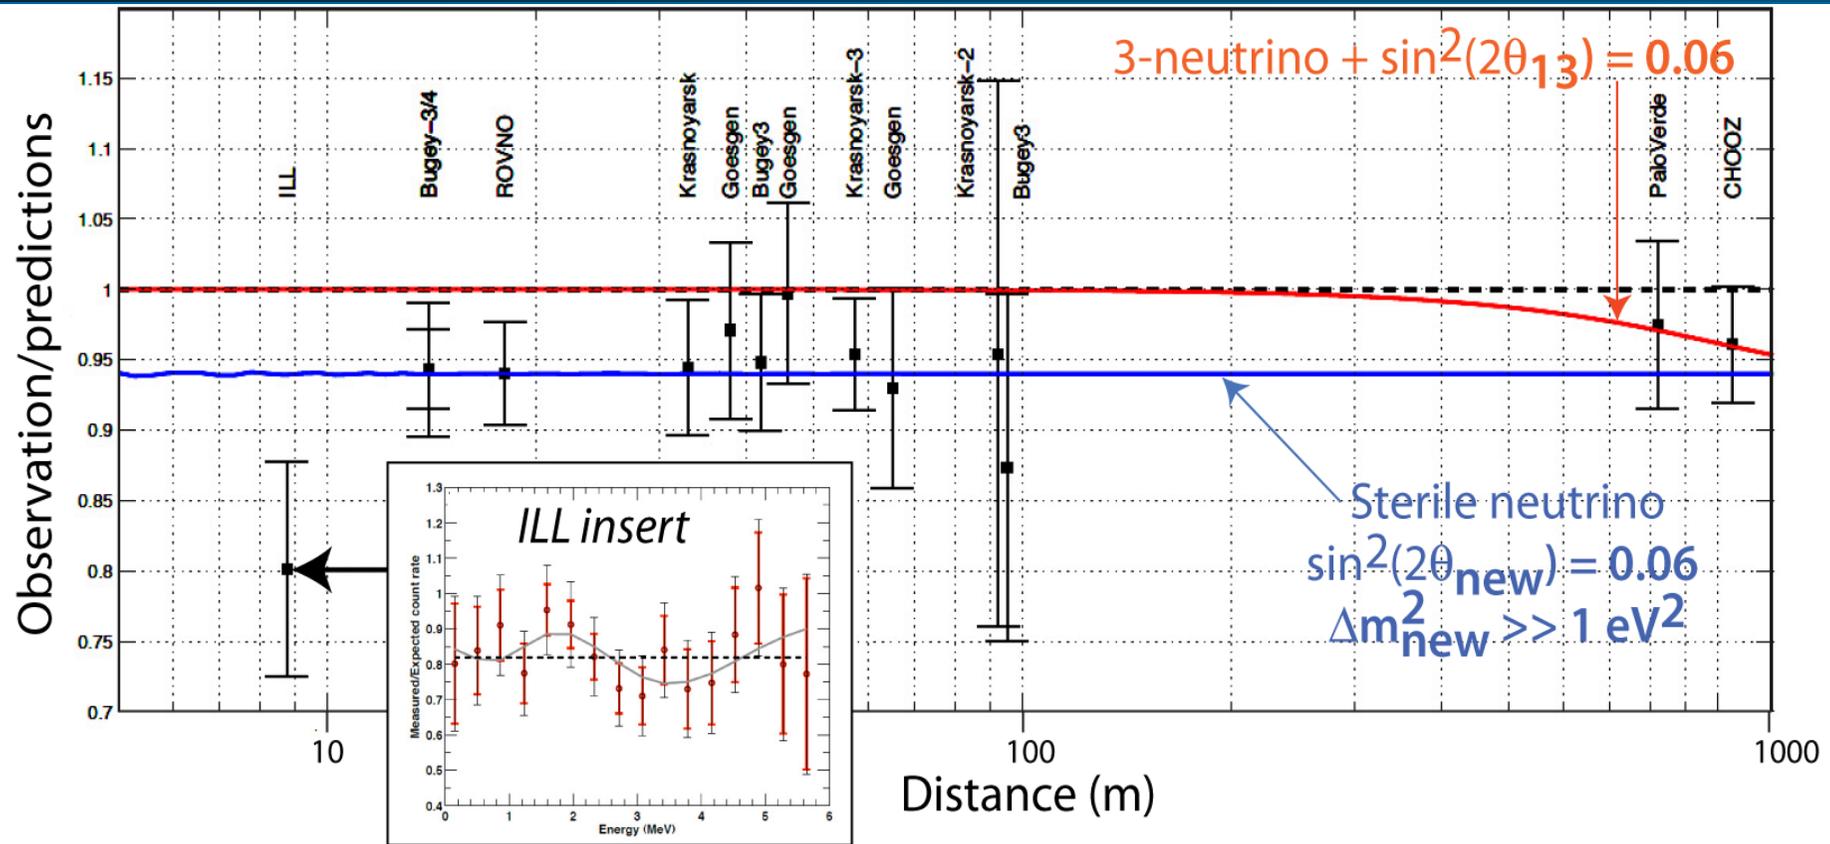

# Sterile neutrinos ?

- The possible presence of oscillations into sterile neutrinos has been proposed by B. Pontecorvo, but so far without conclusion.
- Two distinct classes of anomalies have been observed, namely
  - apparent *disappearance signals*: (1) the anti- $\nu_e$  events detected from near-by nuclear reactors and (2) from the from Mega-Curie k-capture calibration sources in the Gallium experiments to detect solar  $\nu_e$
  - observation for *excess signals* of  $\nu_e$  electrons from neutrinos from particle accelerators (LNSD/MiniBooNE)
- These experiments may all point out to the possible existence of the fourth non standard neutrino state driving oscillations at a small distances, with typically  $\Delta m_{new}^2 \geq 1 \text{ eV}^2$  and relatively large mixing angle with  $\sin^2(2\theta_{new}) \approx 0.1$ .
- The existence of a fourth neutrino state may be also hinted — or at least not excluded — by cosmological data

# The Gallium experiments

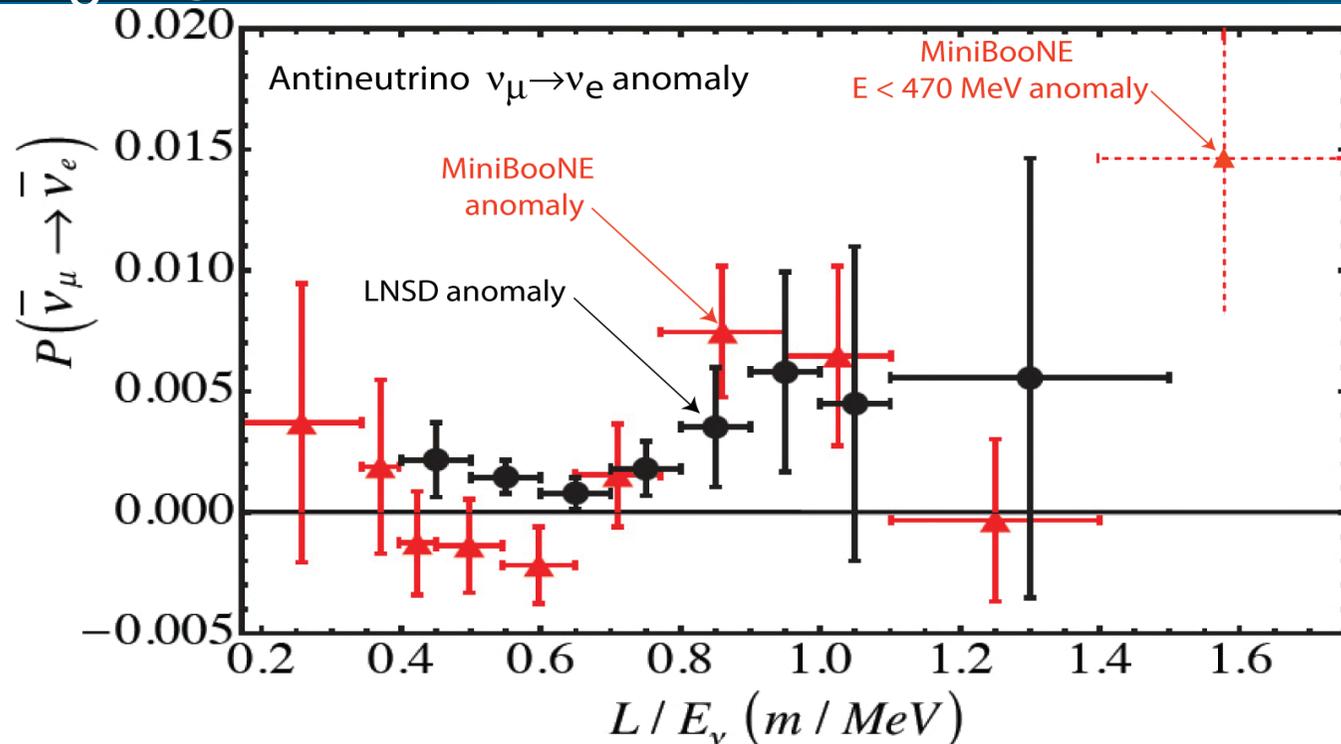

- In the late nineties the *SAGE* and *GALLEX* experiments recorded the calibration signal produced by intense artificial k-capture sources of  $^{51}\text{Cr}$  and  $^{37}\text{Ar}$  near the detector.
- The averaged result of the ratio  $R$  between the source detected and predicted neutrino rates are consistent with each other, giving  $R = (0.86 \pm 0.05)$  about  $2.7\sigma$  away from  $R = 1$
- The result is somewhat influenced by uncertainties in nuclear models, which however may not be enough to bring  $R$  to unity.
- These best fitted values may favour the existence of an undetected sterile neutrino with an evidence of  $2.3\sigma$  and a broad range of values around  $\Delta m_{\text{new}}^2 \approx 2 \text{ eV}^2$  and  $\sin^2(2\theta_{\text{new}}) \approx 0.3$ .

# Disappearance signal: the reactor antineutrino anomaly

- From *G. Mention et al. arXiv:1101.2755v1 [hep-ex]* Experimental results are compared to the prediction without oscillation, taking into account the new spectra, the neutron mean lifetime and the off-equilibrium effects. The averaged ratio is  $0.937 \pm 0.027$ . The **red line** is for  $\sin^2(2\theta_{13}) = 0.06$ . The **blue line** is for a sterile neutrino with  $\Delta m_{new}^2 \gg 1 \text{ eV}^2$  and  $\sin^2(2\theta_{new}) = 0.06$ .

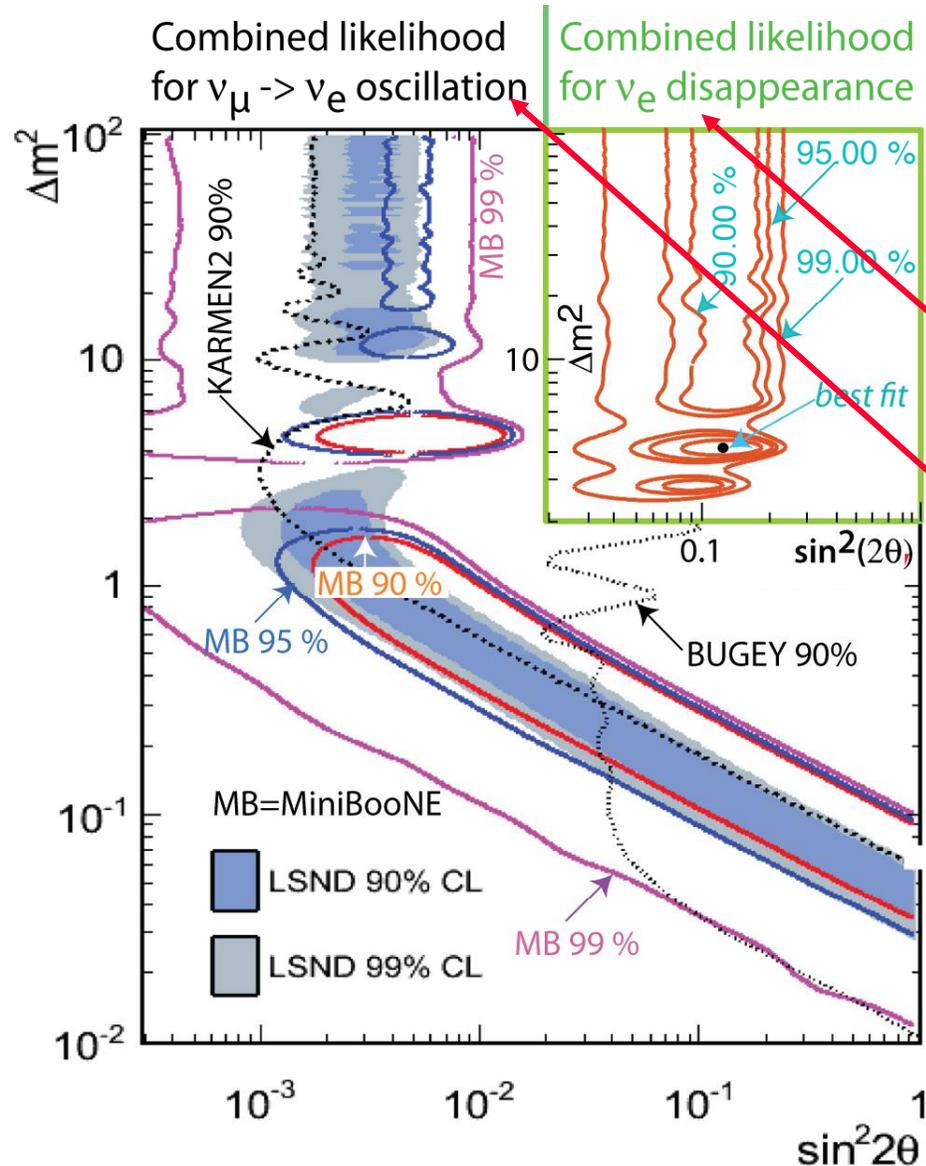

# Excess $\bar{\nu}_e$ signal: The LSND/ MiniBooNE anti-neutrinos

*G.Mills,  
ICHEP,  
July 2010*

- The more recent MiniBooNE antineutrino run has shown the direct presence of a LSND like anomaly for neutrino energies  $> 430$  MeV. The result is compelling with respect to the ordinary two-neutrino fit, indicating a 99.4% probability for an anomalous excess in  $\bar{\nu}_e$  production.
- The reported effect is broadly compatible with the expectation of LSND experiment, which, as well known, was originally dominant in the antineutrino channel.

# A unified approach ?

Allowed regions in the plane for combined results:

- the  $\nu_e$  disappearance rate (right)
- the LSND / MiniBooNE anti- $\nu_e$  anomaly (left).

While the values of  $\Delta m^2_{new}$  may indeed have a common origin, the different values of  $\sin^2(2\theta_{new})$  may reflect within the  $\geq 4$  neutrinos hypothesis and a mass matrix  $U_{(4,k)} \approx 0.1$ , where  $k = \mu$  and  $e$ .

# The need of imaging detectors of high target density

The success of bubble chamber as main tool in H.E. fixed target physics is due to two facts:

- it provides a massive homogeneous target, of substantial density
- it provides complete imaging/reconstruction of events in itself

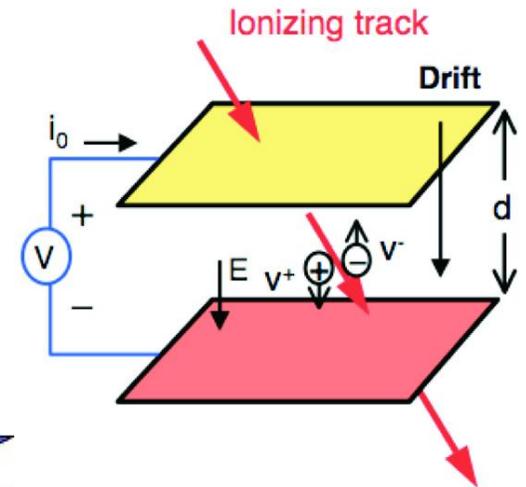

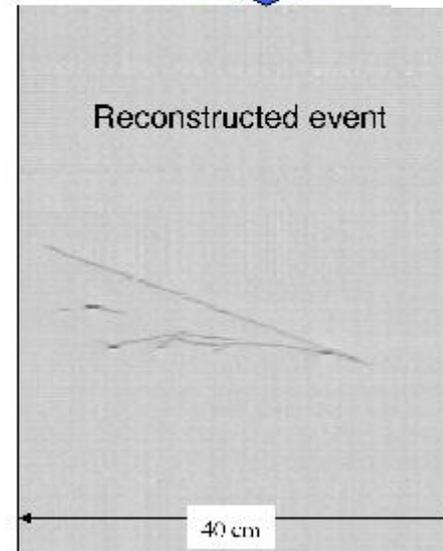

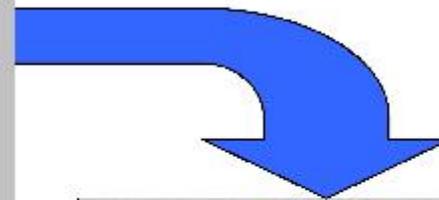

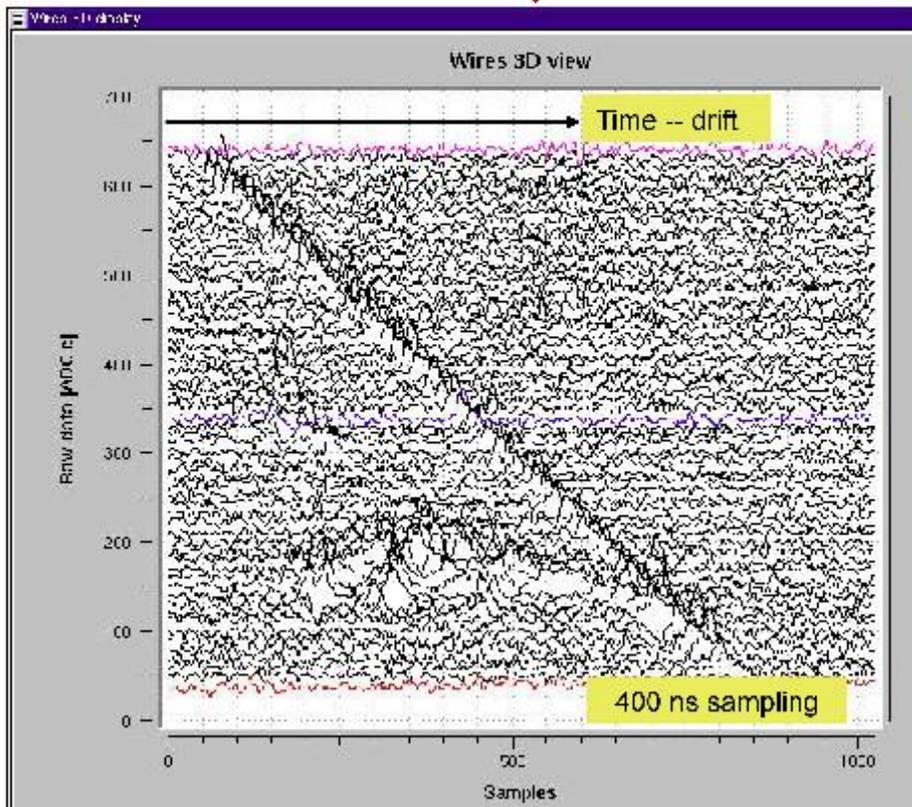

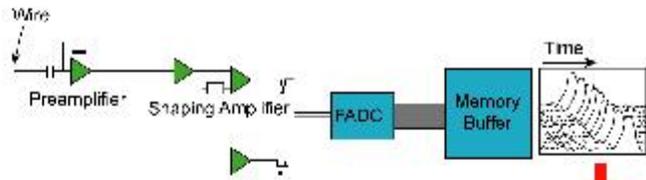

This technology permitted in the past very substantial advances in Physics based on

- single event with complete reconstruction (i.e.  $\Omega^-$  discovery)
- surprise events, i.e. topologies not a priori expected (e.g. Neutral Current)

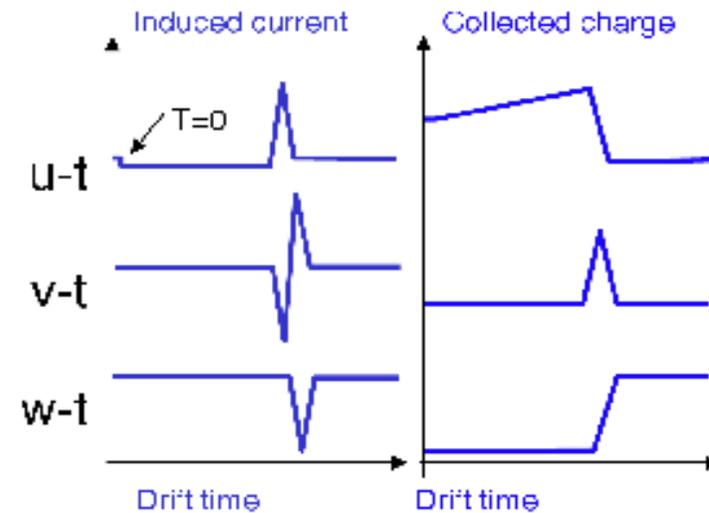

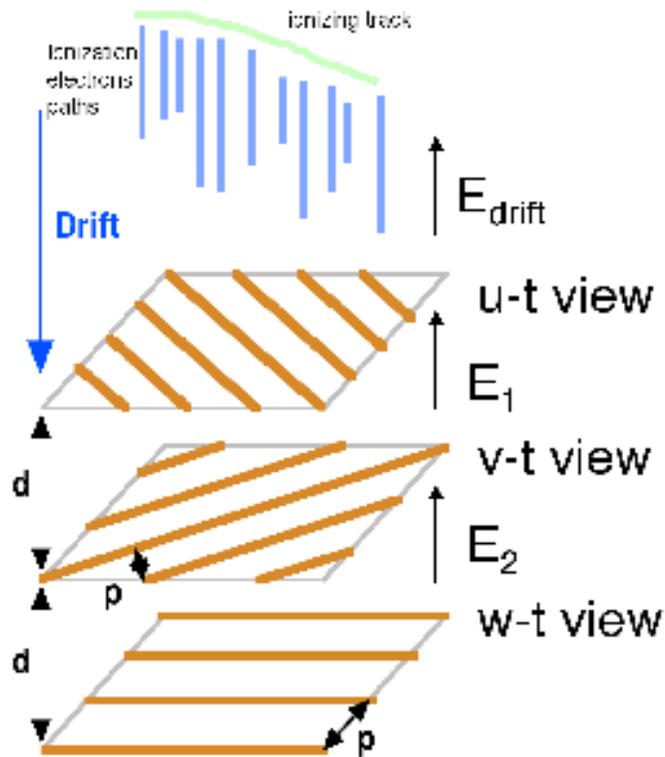

However this technology is costly/complicated,  
non expandable to large masses...

# Collecting a track charge

# Non destructive readout: the induction signals (3D) !

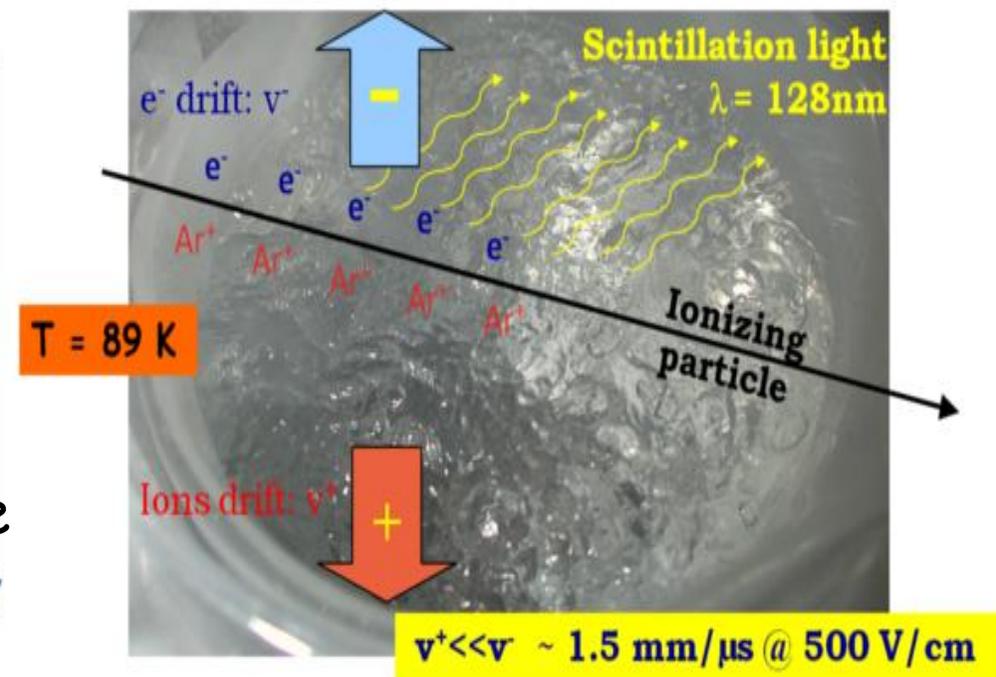

*With at least 3 views, a three-dimensional localization of position for each value of  $t$*

Drifting electrons are traversing 3 transparent wire arrays oriented in direction of the required view. The ionizing track records in each plane a triangular induction signal. Finally electron charge is collected by the last "Collection plane". The generated topological view of the event is the one seen by a camera at infinity with the optical axis in direction of wires.

# LAr: a noble liquid as target/tracking medium

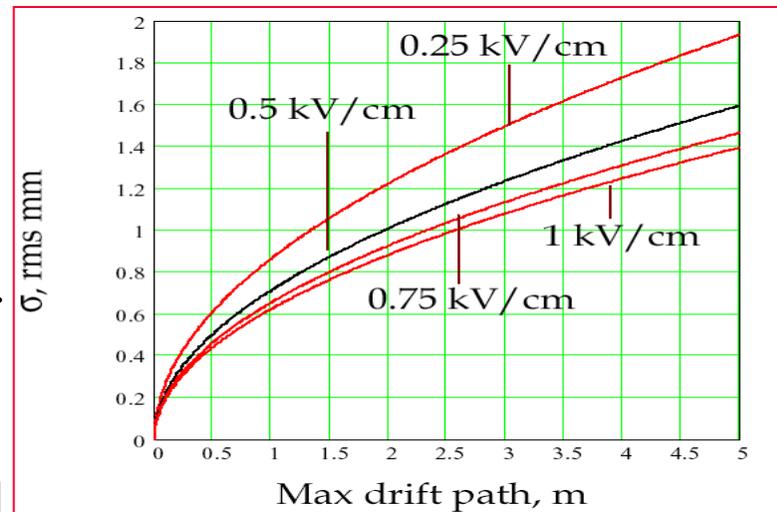

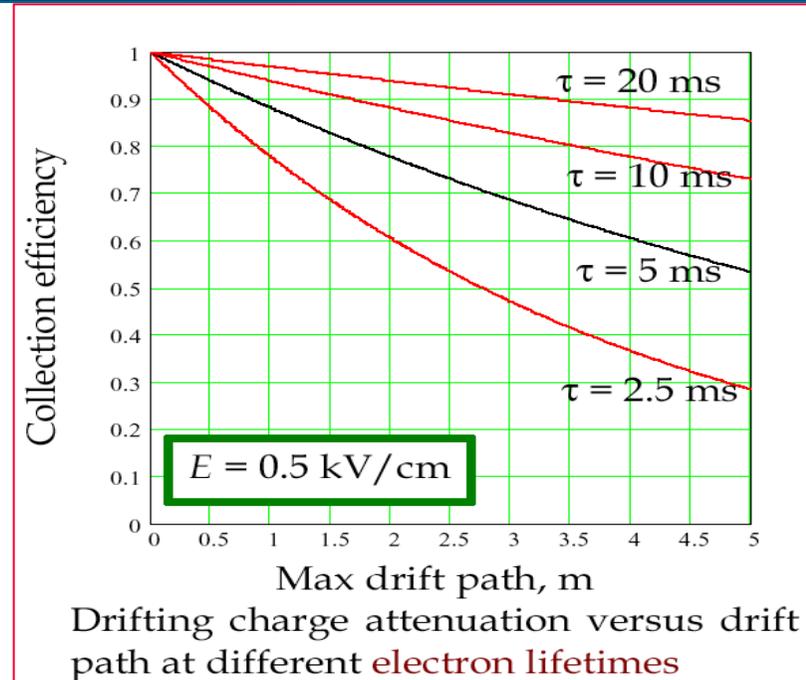

Ideal material, commercially easy to obtain (1 % of air content), for detection of ionizing radiation:

- Dense (1 g/cm<sup>3</sup>), homogeneous, it acts as target and detector
- High electron mobility, does not attach electrons (long drift path in liquid)
- Inert, not flammable can be made very pure (impurities can be frezed out)
- Ionization: 42000 e<sup>-</sup> - ion/MeV
- Scintillation light: 104 g/MeV, UV spectrum  $\lambda = 128 \text{ nm}$ , LAr is transparent, no successive ionizations because low energy
- Cherenkov light (if fast particle)

# Free electron signal in LAr

- The strong  $e^-$ -ion recombination due to comparable thermalisation distance (140 nm) and separation is reduced to 30% for  $E_{\text{drift}} = 500 \text{ V/cm}$
- The presence of  $e^-$ -trapping impurities attenuates electron signal as  $\exp -t/t_{\text{ele}}$ : it can be expressed in equivalent Oxygen molar densities:  $\tau_{\text{ele}} = 300 \text{ ms } 1 \text{ ppb}/N(\text{O}_2)$
- Because of temperature (87 K) most of contaminants freeze out spontaneously. Main residuals:  $\text{O}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{CO}_2$  and  $\text{N}_2$ . Goal: 10 ms lifetime for a 30 ppt ( $t = \text{trillion!}$ ) of  $\text{O}_2$  equivalent!
- At 500 V/cm, 5 m drift corresponds to 3.1 ms drift time ( $v_D = 1.6 \text{ m/ms}$ )
- Intrinsic bubble size (diffusion) tiny w.r.t. 3 mm pitch: 1 mm r.m.s. after 5 m of drift!

Slide: 20

2001: First T600 module

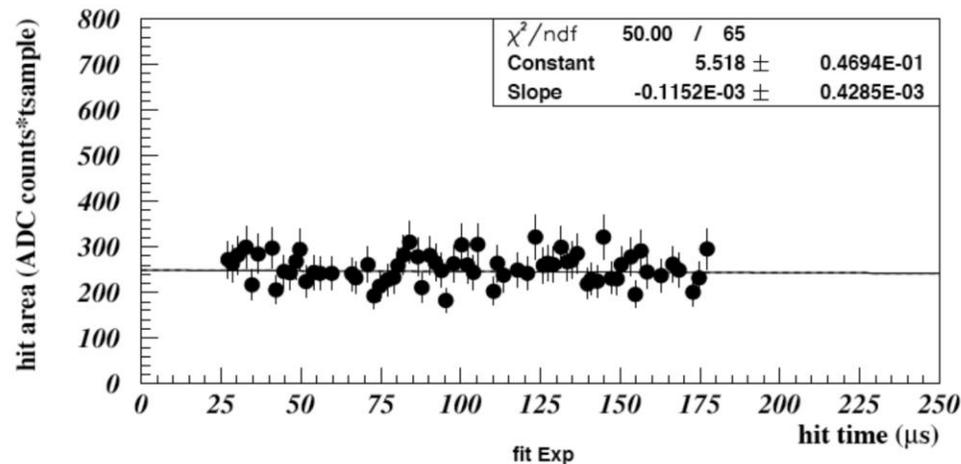

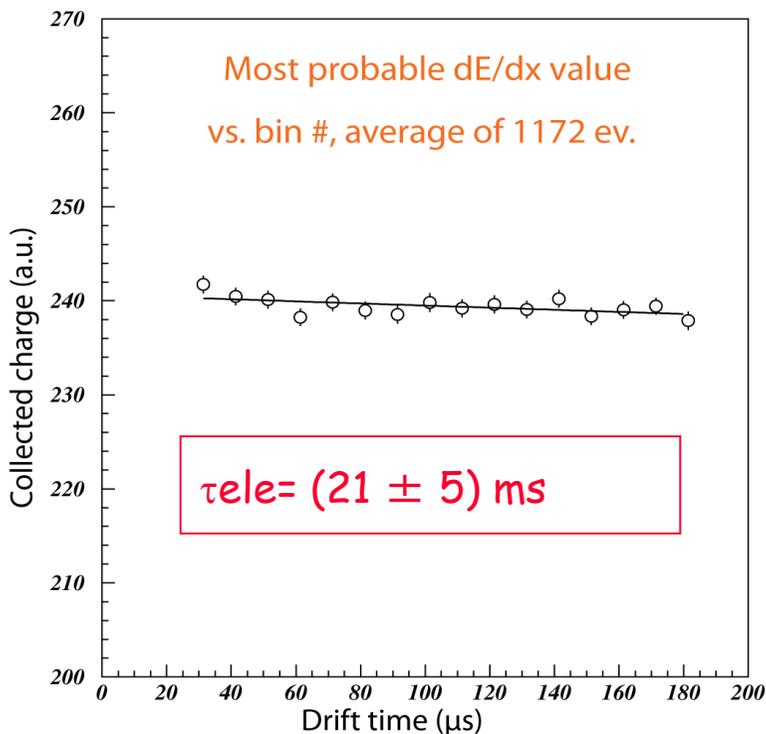

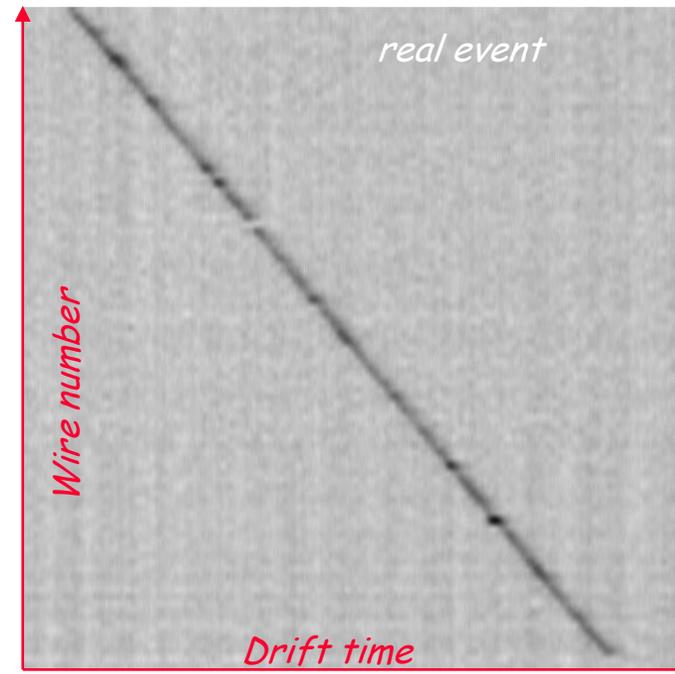

# Recent progress in experimental purity achievements

- New industrial purification methods have been developed at an exceptional level, especially remnants of  $O_2$  which have to be initially and continuously purified.
- Extremely high  $\tau_{ele}$  have been determined with cosmic  $\mu$ 's in a small 50 litres LAr-TPC.
- The short path length used (30 cm) is compensated by the high accuracy in the observation of the specific ionization
- The result here reported is  $\tau_{ele} \approx 21$  ms corresponding to 15 ppt, namely  $\approx 10^{-11}$  molecular impurities in Ar

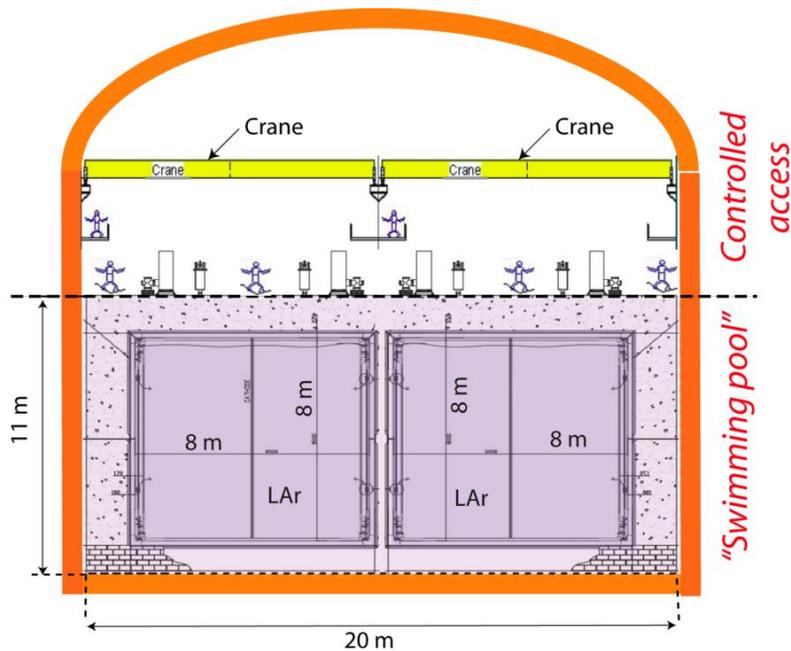

# ICARINO-Legnaro

- The measured value to the experimental  $\tau_{ele}$  corresponds to an attenuation of about 10 % for a longest drift of 5 meters, opening the way to exceptionally long drift distances.

# Toward 20 kton LAr-TPC: MODULAR project

- The achieved milestones open the way to development of new line of modular elements, which may be progressively extrapolated to the largest conceivable LAr-TPC sensitive masses.
- Based on the T600 experience, the ICARUS collaboration has now proposed a next generation LAr-TPC in tens of kt scale: **the MODULAR project**. (*Astroparticle Physics* 29 (2008) 174)
- New 20 kt detector, using the present CNGS beam off axis with 5 kton units will maintain the majority of components developed with industry for T600.

# LAr-TPC performance -1

- Tracking device:
  - precise event topology ( $\sigma_{x,y} \sim 1\text{mm}$ ,  $\sigma_z \sim 0.4\text{mm}$ )
  - $\mu$  momentum measurement via multiple scattering:  $\Delta p/p \sim 10\text{-}15\%$  depending on track length and  $p$
- Measurement of local energy deposition  $dE/dx$ :
  - $e/\gamma$  separation (2%  $X_0$  sampling);
  - particle ID by means of  $dE/dx$  vs range
  - $e/\pi^0$  discrimination at  $10^{-3}$  by  $\gamma$  conversion from vertex,  $\pi^0$  mass and  $dE/dx$  measurements (90 % electron identification efficiency)
- Total energy reconstruction by charge integration:
  - full sampling, homogeneous calorimeter with excellent accuracy for contained events

## RESOLUTIONS

Low energy electrons:  $\sigma(E)/E = 11\% / \sqrt{E(\text{MeV})} + 2\%$

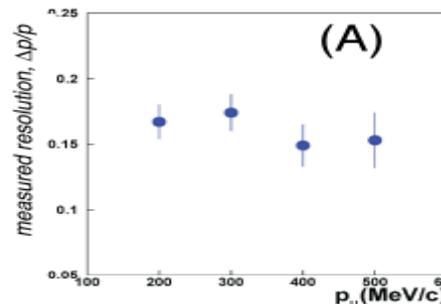

Electromagnetic showers:  $\sigma(E)/E = 3\% / \sqrt{E(\text{GeV})}$

Hadron shower (pure LAr):  $\sigma(E)/E \approx 30\% / \sqrt{E(\text{GeV})}$

# LAr-TPC performance -2

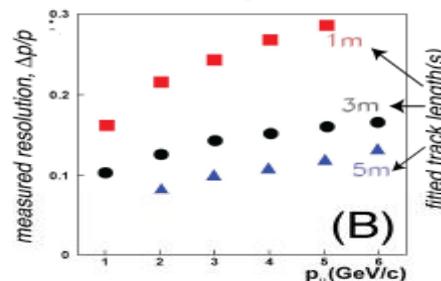

- (A) momentum resolution of stopping muons;
- (B) momentum resolution of traversing  $\mu$  with the Kalman filter method:  $p$  is extracted from measurement of deflection angle  $\phi$  and from  $\chi^2$  of the fit.
- (C)  $dE/dx$  energy loss for slow  $\pi$  (green) and protons (red);
- (D) Michel electron decay spectrum from  $\mu \rightarrow e$  decays;
- (E)  $\pi^0 \rightarrow 2\gamma$  reconstruction and mass determination;
- (F) mass spectrum of 230 interactions with  $\gamma\gamma$  candidates.

- ❑ **ICARUS T600: major milestone** towards realization of large scale LAr detector. Interesting physics in itself: unique imaging capability, spatial/calorimetric resolutions and  $e/\pi^0$  separation → events “seen in a new Bubble chamber like” way.
- ❑ CNGS  $\nu$  events (beam intensity  $4.5 \cdot 10^{19}$  pot/year,  $E_\nu \sim 17.4$  GeV):
  - 1200  $\nu_\mu$  CC event/year;
  - $\sim 8$   $\nu_e$  CC event/year;
  - observation of  $\nu_\tau$  in electron channel, with kinematical criteria;
  - search for sterile  $\nu$  in LSND parameter space (deep inelastic  $\nu_e$  CC events excess).
- ❑ “Self triggered” events collection:
  - $\sim 80$  events/y of unbiased atmospheric  $\nu$  CC;
  - zero bkg proton decay,  $3 \times 10^{32}$  nucleons for “exotic” channels.

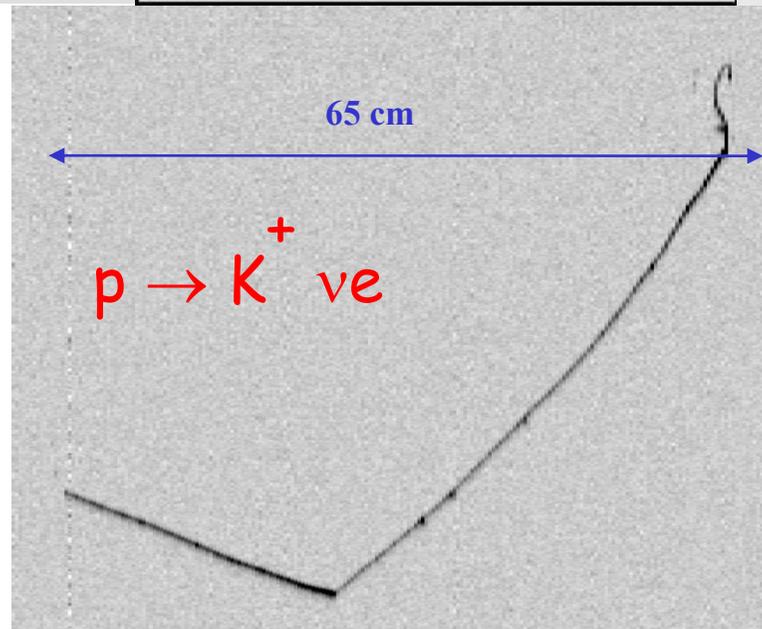

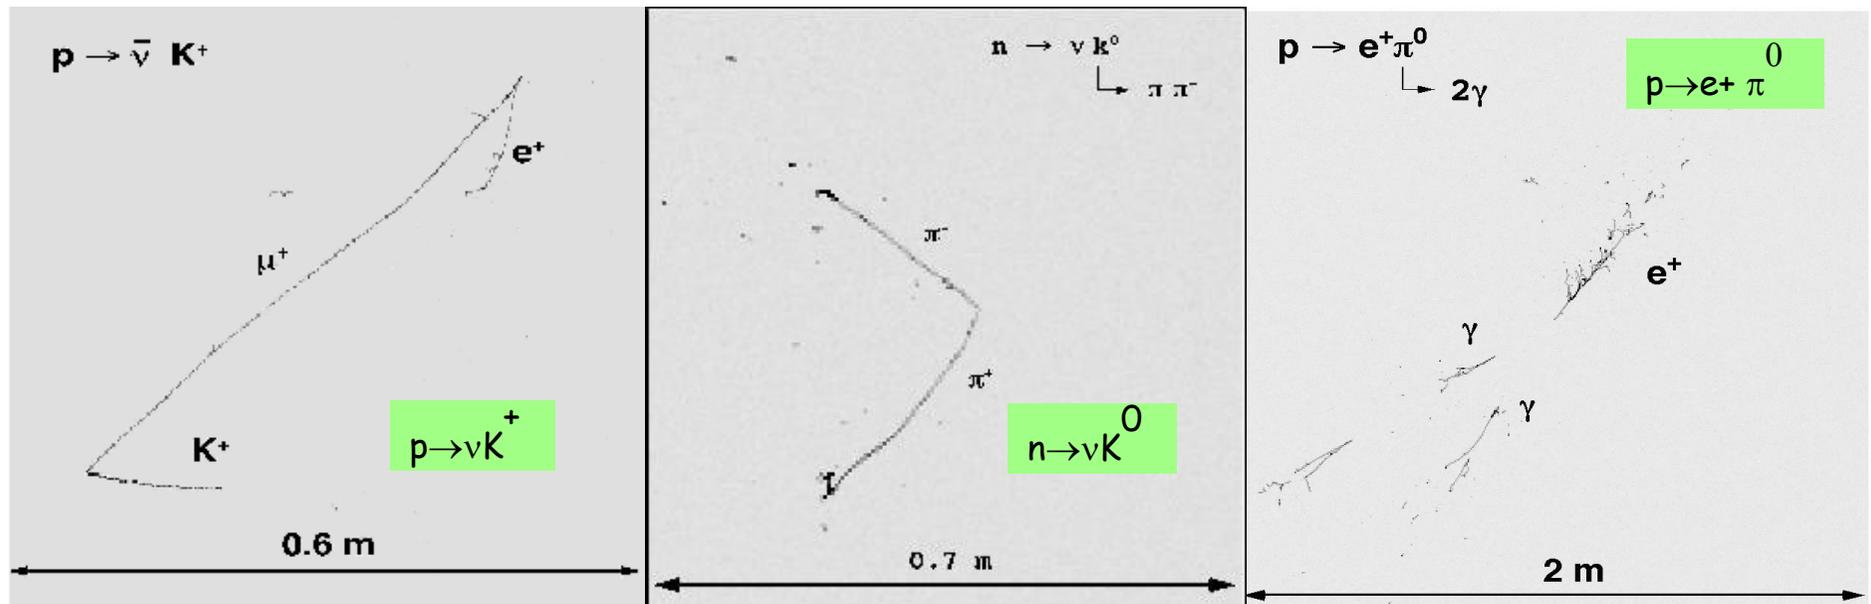

# Nucleon decay search

- $3 \cdot 10^{32}$  nucleons
- Several bkg-free channels: the experimental sensitivity increases linearly with the exposition time

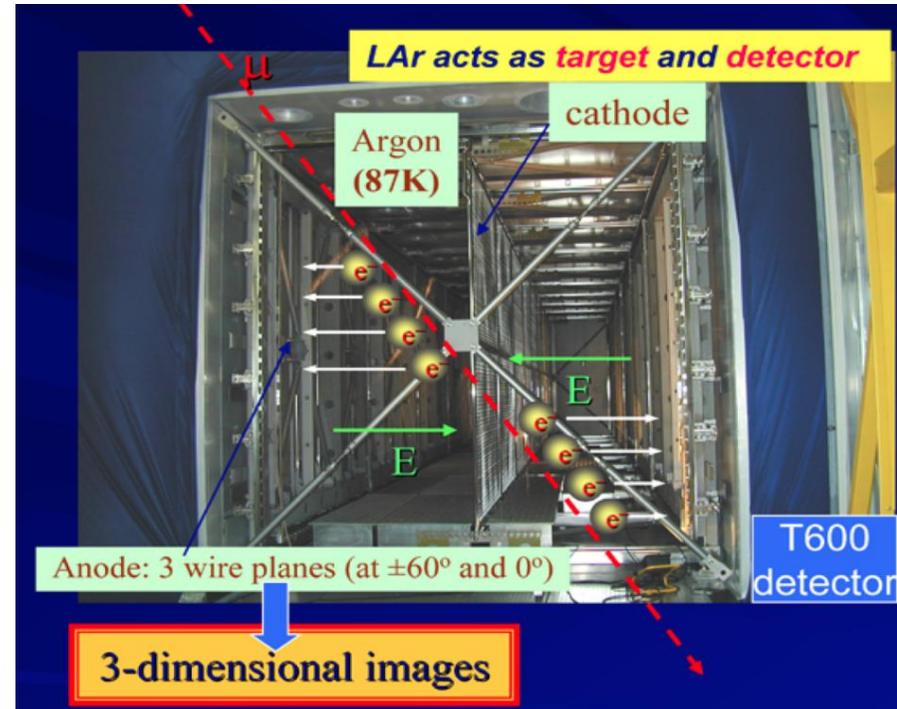

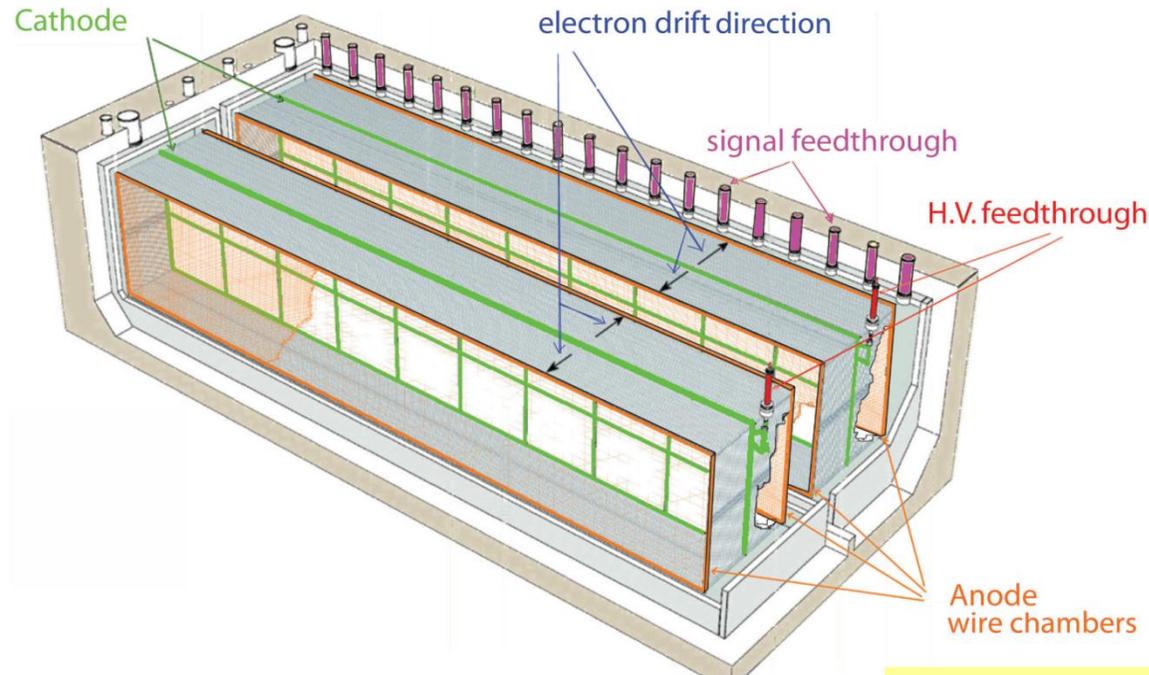

Decay channel	PDG limit [10 <sup>31</sup> anni]	T600 yrs to reach PDG limit
$n \rightarrow e^- K^+$	3,2	0,5
$p \rightarrow \pi^+ \bar{\nu}$	2,5	1,1
$n \rightarrow \mu^+ \pi^-$	10,0	3,3
$p \rightarrow \mu^- \pi^+ K^+$	24,5	4,5
$n \rightarrow \pi^0 \bar{\nu}$	11,2	5,1
$n \rightarrow e^+ \pi^-$	15,8	5,3

# Nucleon decay : single event capability

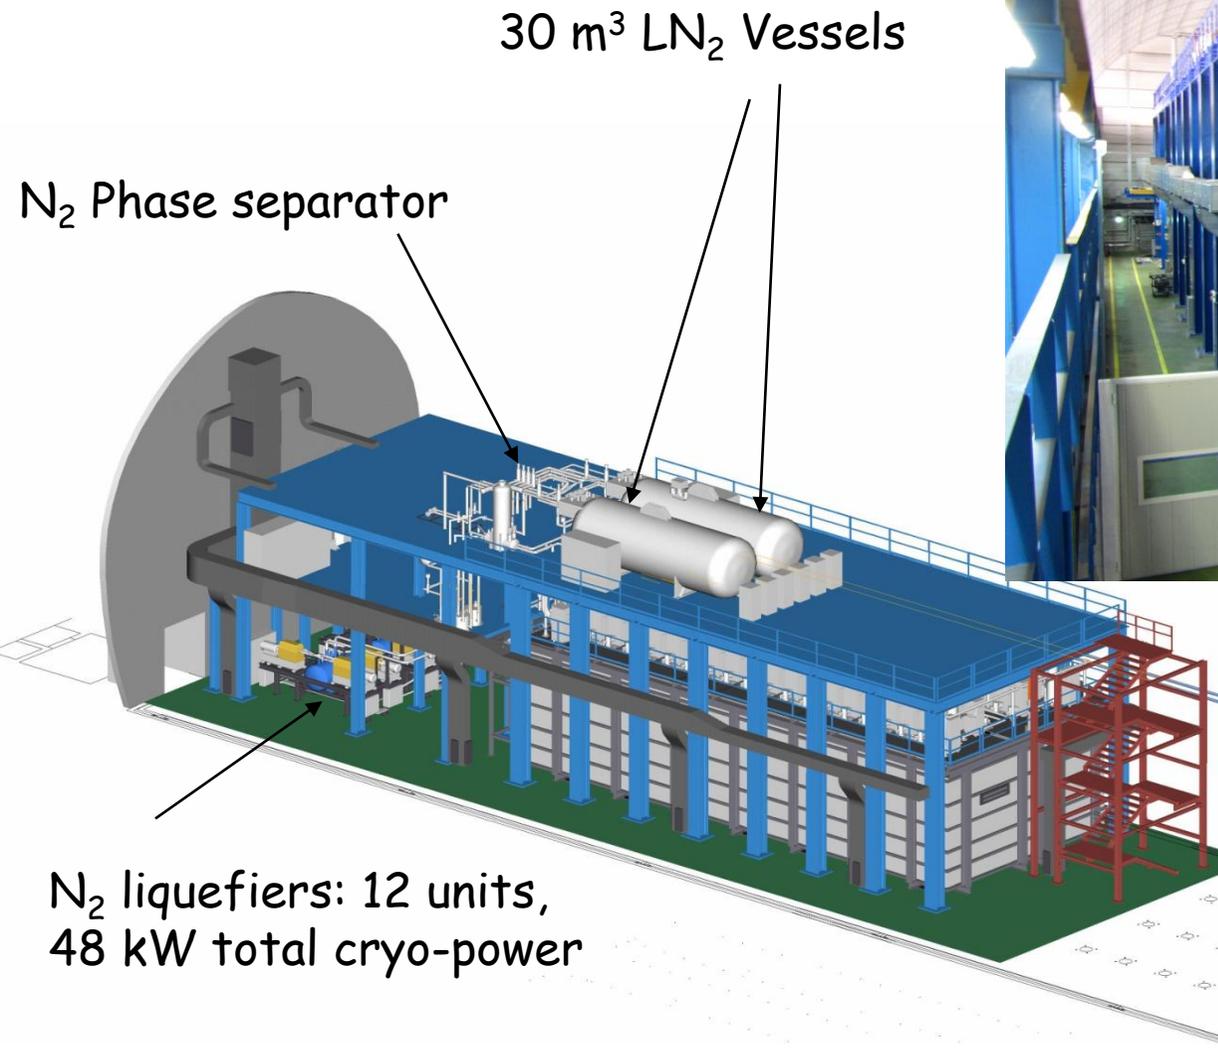

# ICARUS T600: the first large scale LAr detector

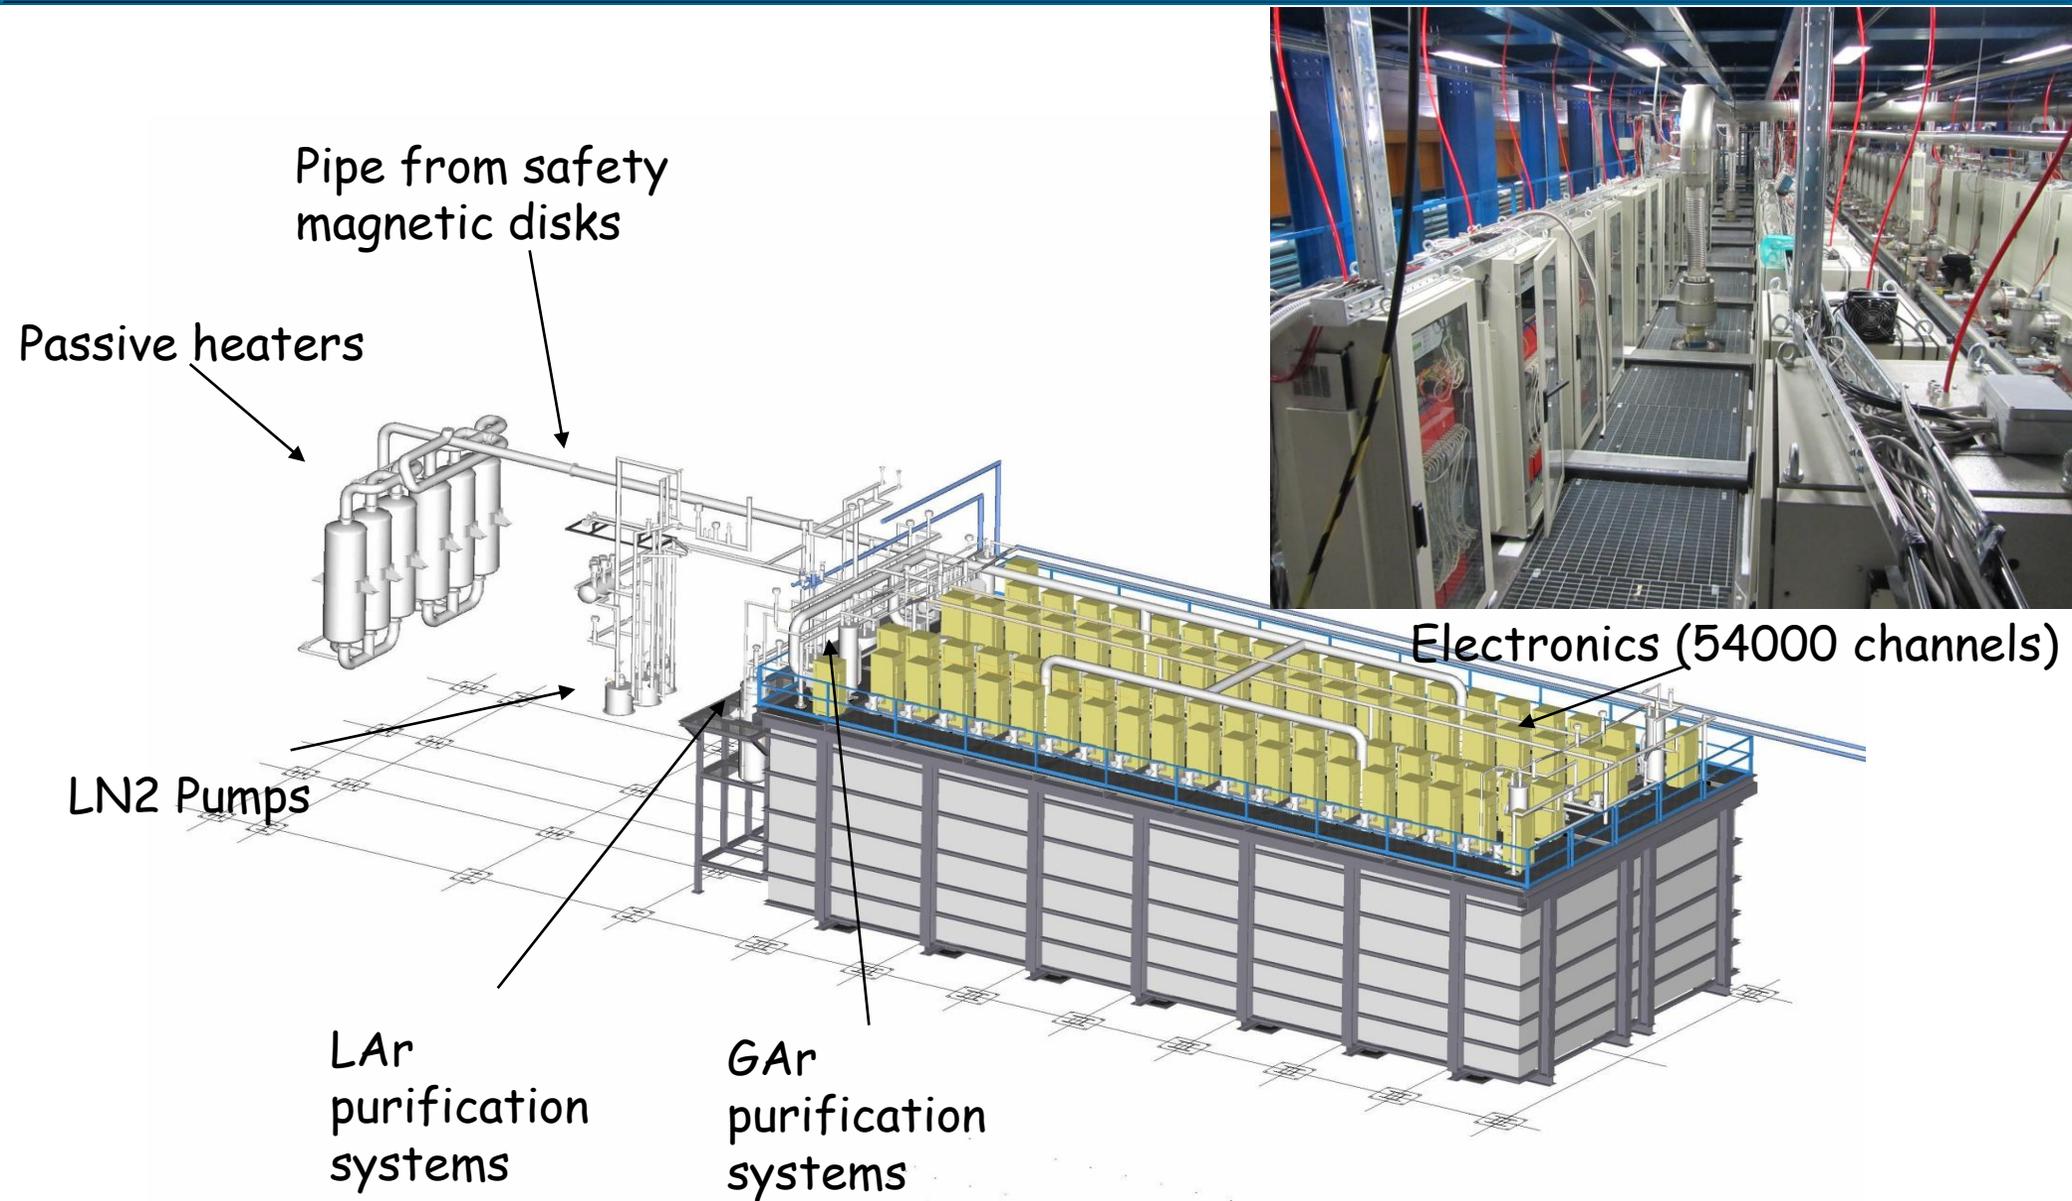

- Two identical modules
  - $3.6 \times 3.9 \times 19.6 \approx 275 \text{ m}^3$  each
  - Liquid Ar active mass:  $\approx 476 \text{ t}$
  - Drift length = 1.5 m
  - HV = -75 kV  $E = 0.5 \text{ kV/cm}$
  - $v_{\text{drift}} = 1.55 \text{ mm}/\mu\text{s}$

- 4 wire chambers: 2 chambers per module
  - 3 readout wire planes per chamber, wires at  $0, \pm 60^\circ$
  - $\approx 54000$  wires, 3 mm pitch, 3 mm plane spacing
- (20 + 54) PMTs, 8"  $\varnothing$  for scintillation light:
  - VUV sensitive (128nm) with wave shifter (TPB)

# ICARUS T600 in LNGS Hall B

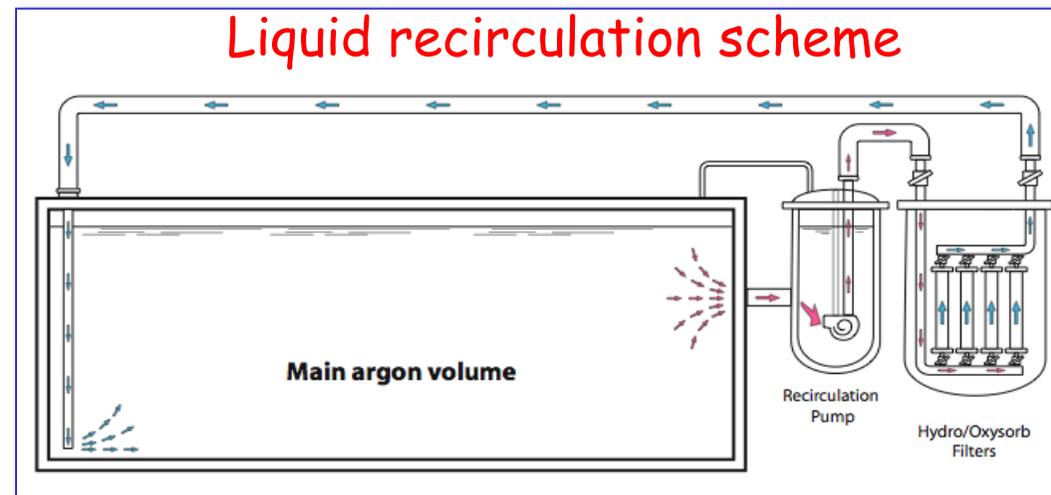

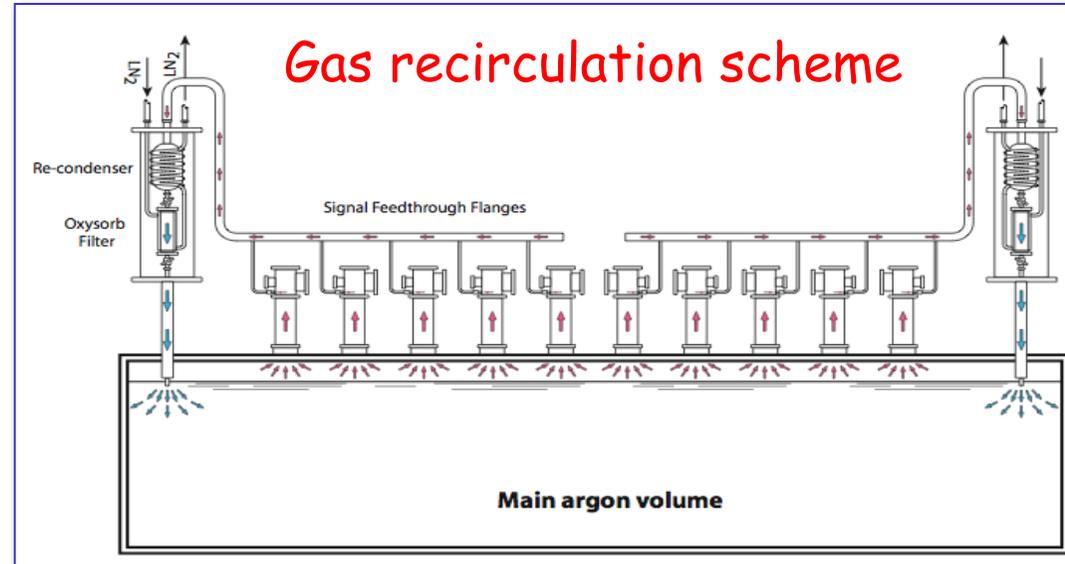

# T600 cryostats layout

# LAr Purification in T600

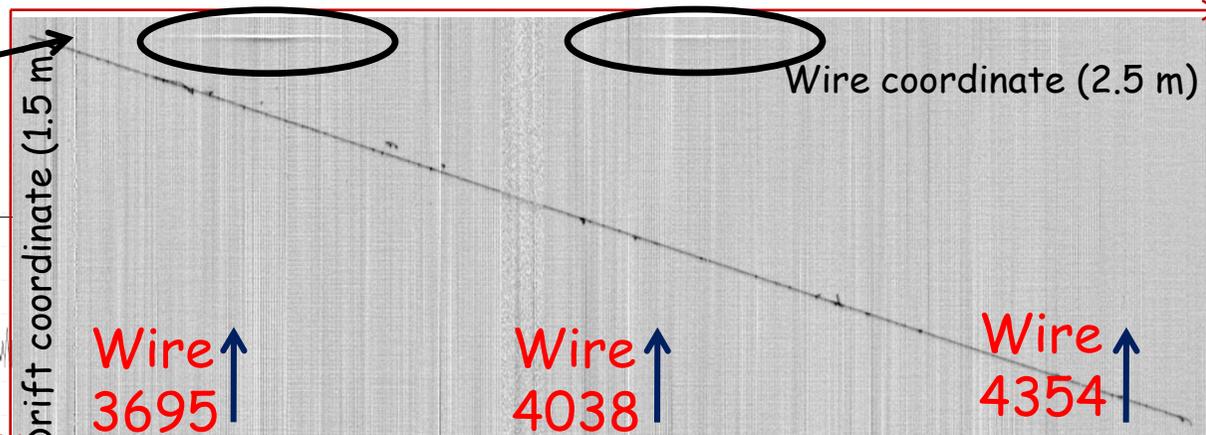

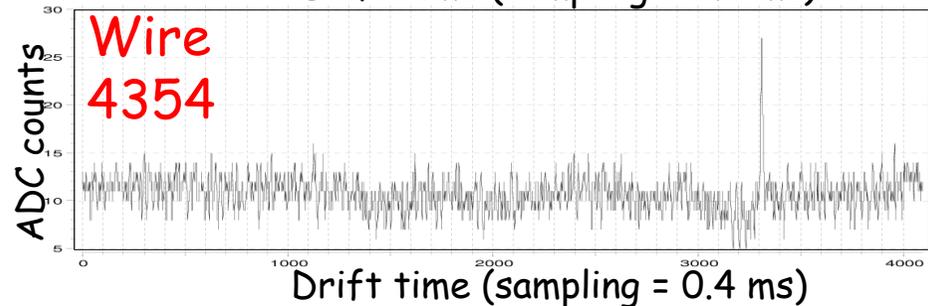

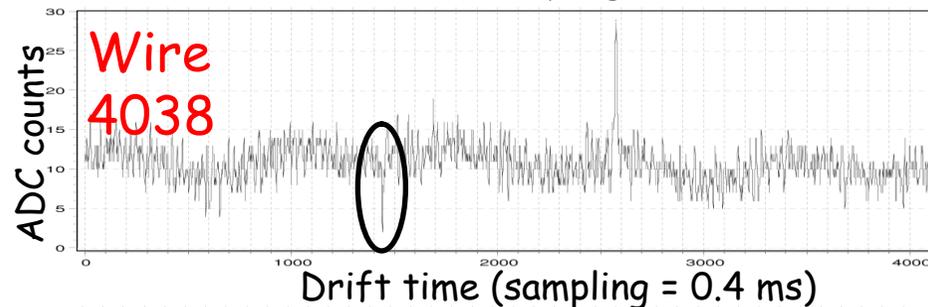

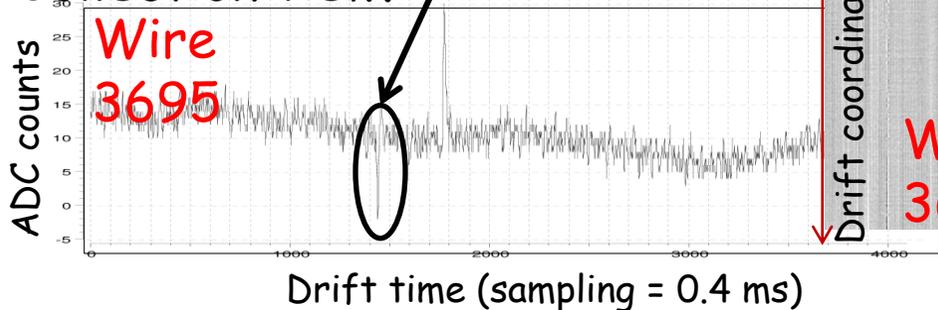

- Recirculation/purification (100 Nm<sup>3</sup>/h) of the gas phase (~40 Nm<sup>3</sup>) to block diffusion of the impurities from the hot parts of the detector and from micro-leaks on the openings (typically located on the top of the device) into the bulk liquid.
- Recirculation/purification (4 m<sup>3</sup>/h) of the bulk liquid volume (~550 m<sup>3</sup>) to efficiently reduce initial impurities (can be switched on/off).

# LAr purity measurement with muon crossing tracks

Charge attenuation along track allows event-by-event measurement of LAr purity.

~ 1.5 ADC # (1500 electrons)

# LAr purity time evolution

Simple model: uniform distribution of the impurities, including internal degassing, decreasing in time, constant external leak and liquid purification by recirculation.

$$dN/dt = -N/t_R + k + k_I \exp(-t/t_I)$$

$$\tau_{ele} [\text{ms}] = 0.3 / N[\text{ppb O}_2 \text{ equivalent}]$$

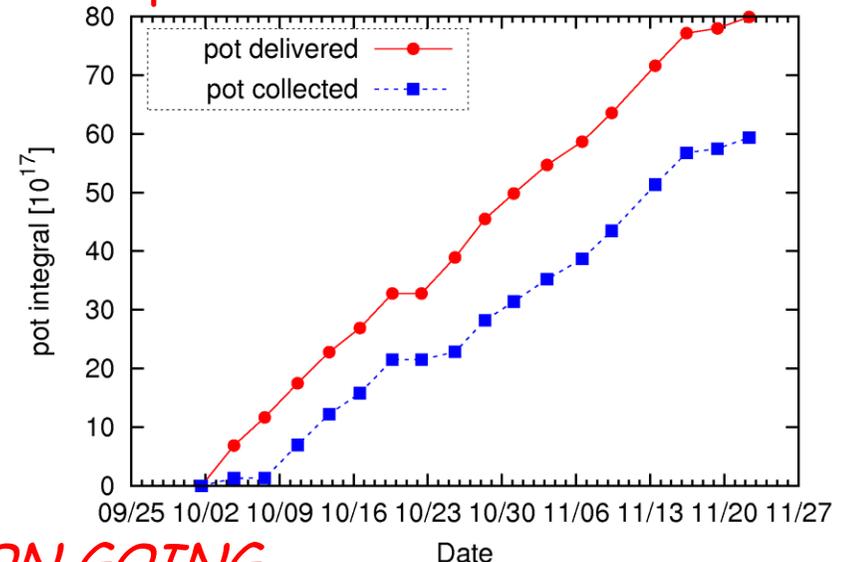

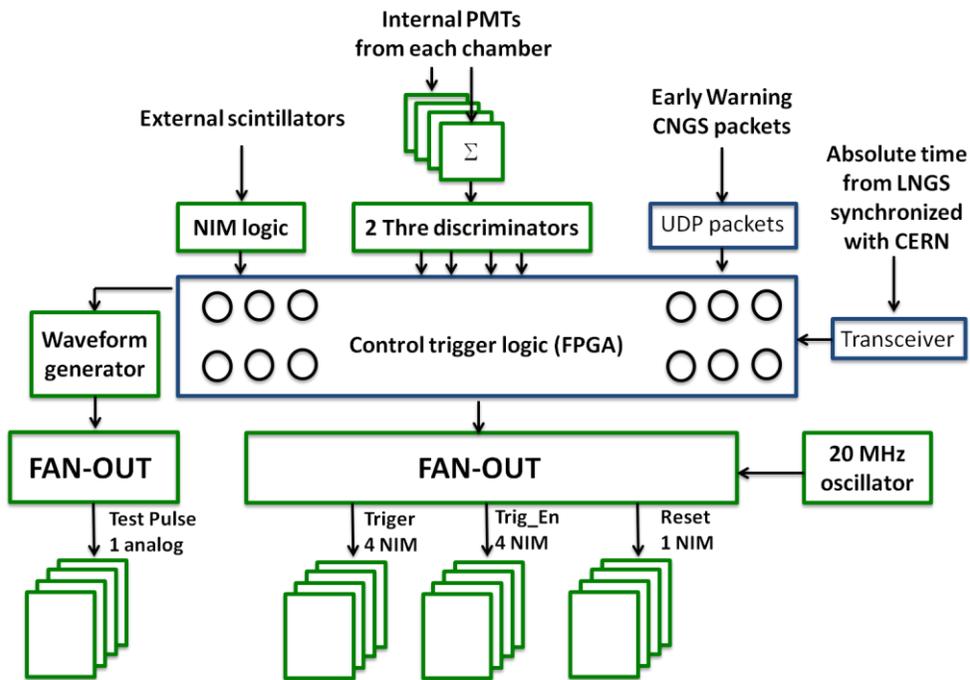

$\tau_R$ : 2 m<sup>3</sup>/h corresponding to  $\approx$  6 day cycle time

$\tau_R$ : recirculation time for a full detector volume  
 $k_I$  and  $\tau_I$ : related to the total degassing internal rate  
 $k$ : related to the external leaks

# CNGS run during 2010

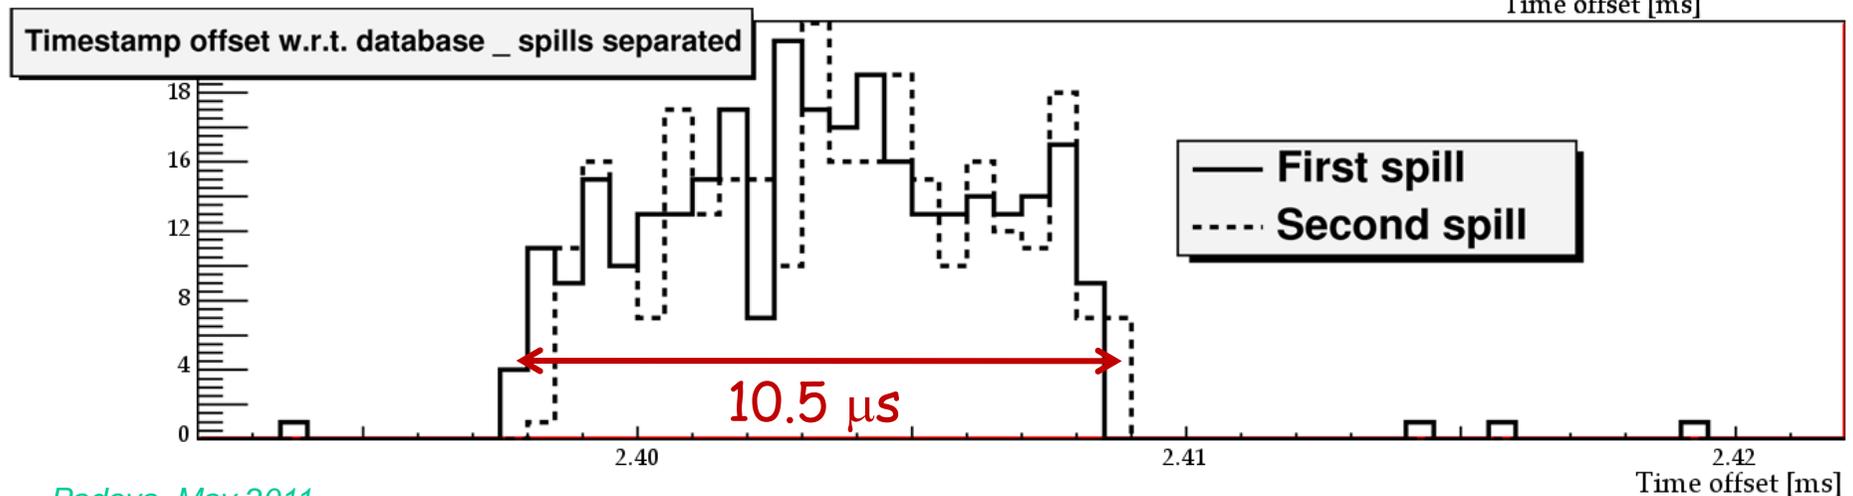

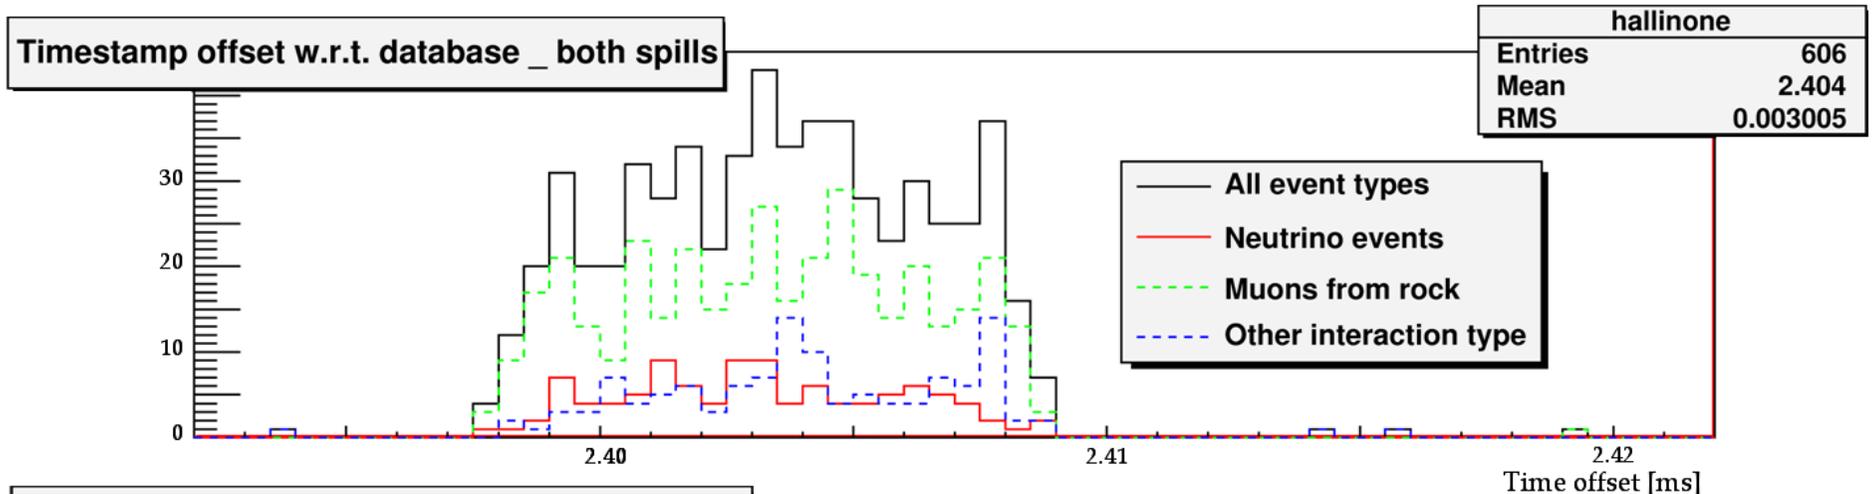

- ❑ ICARUS fully operational for CNGS events recording in Oct. 1<sup>st</sup> - Nov. 22<sup>nd</sup>.
- ❑ At every CNGS cycle 2 spills lasting 10.5  $\mu$ s each, 50 ms apart; ppp =  $2.1 \cdot 10^{13}$ .
- ❑ CNGS "Early Warning" signal sent 80 ms before the proton spill extraction, containing information on the time foreseen for the next extraction.
- ❑ Trigger: photomultiplier signal for each chamber with low threshold discrimination at 100 phe, within 60  $\mu$ s wide beam gate.

Oct. 1<sup>st</sup> ÷ Nov. 22<sup>nd</sup>:  $8 \cdot 10^{18}$  ( $5.8 \cdot 10^{18}$ )  
 pot delivered (collected). Detector  
 lifetime up to 90% since Nov. 1<sup>st</sup>.

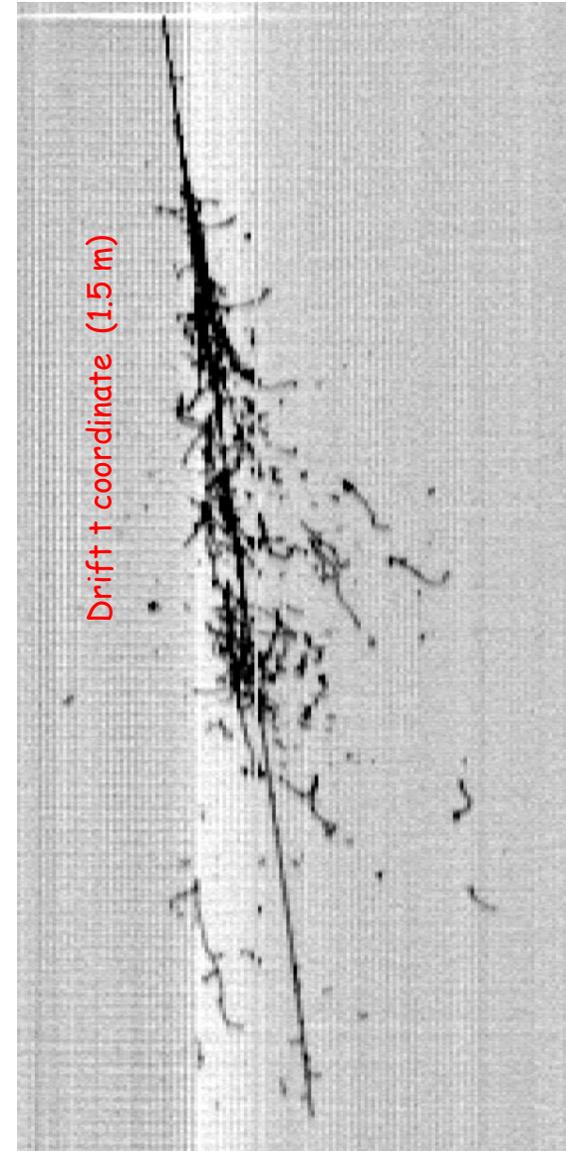

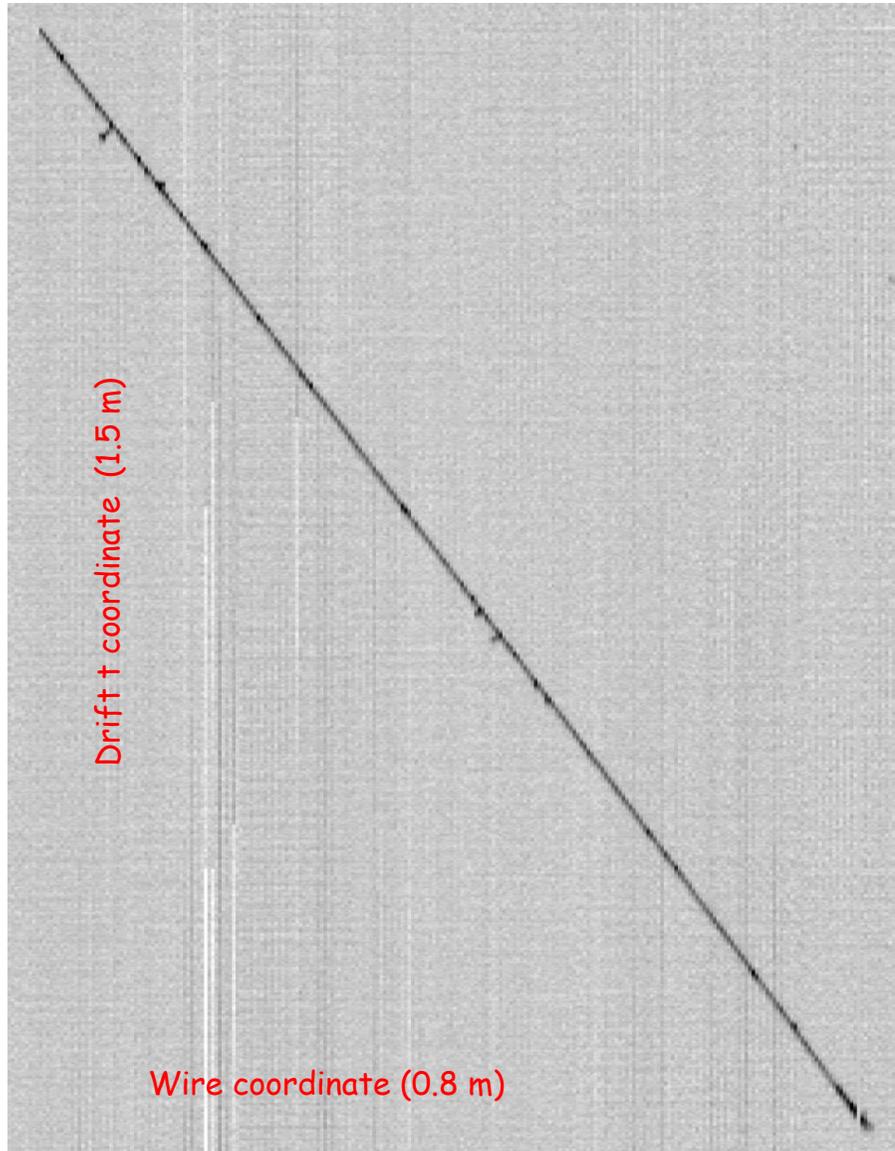

# CNGS events timing w.r.t. p extraction time

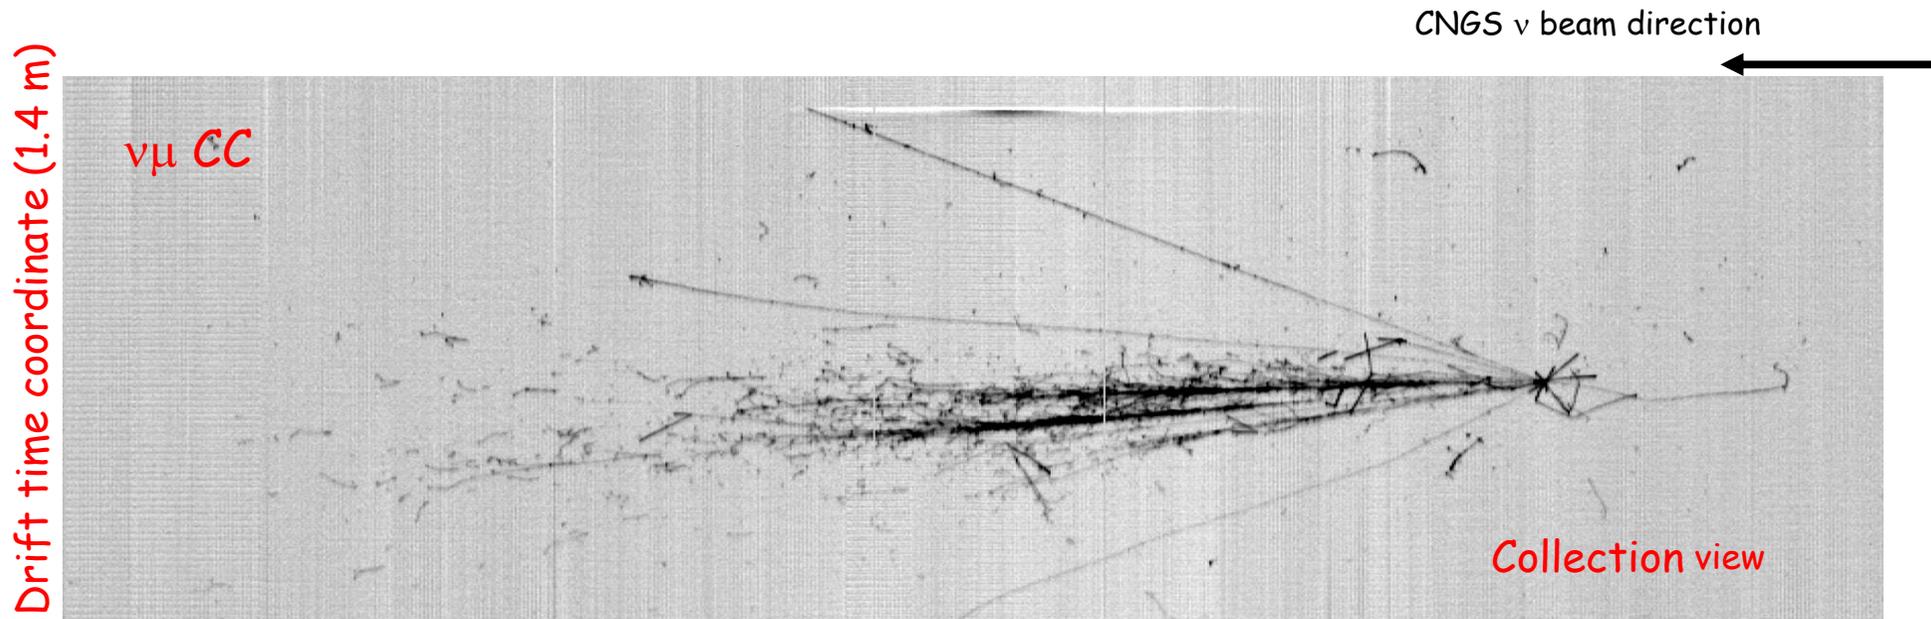

- Narrow distribution  $\sim$  spill duration ( $10.5 \mu\text{s}$ )
- Minimum offset value ( $2.40 \text{ ms}$ ) in agreement with  $\nu$  t.o.f. ( $2.44 \text{ ms}$ ) in view of  $40 \mu\text{s}$  fiber transit time from external LNGS labs to Hall B ( $8\text{km}$ ).

# Outline of the 3D reconstruction

- Complement of 2D reconstruction
  - It is based on Polygonal Line Algorithm (PLA) [1]
  - Procedure of sorting hits along 2D tracks independently in each view
- As a result of the PLA application
  - PLA-fit through hits of a track
  - both hits and hit projections to the fit are sorted along the track
- 3D reconstr.: Linking hit projections between views according to
  - drift sampling
  - sequence of hits

[1] <http://www.iro.umontreal.ca/~kegl/research/pcurves/>

# Polygonal Line Algorithm

$$G(\mathbf{v}_i) = \frac{1}{n} \Delta_n(\mathbf{v}_i) + \lambda \frac{1}{k+1} P(\mathbf{v}_i)$$

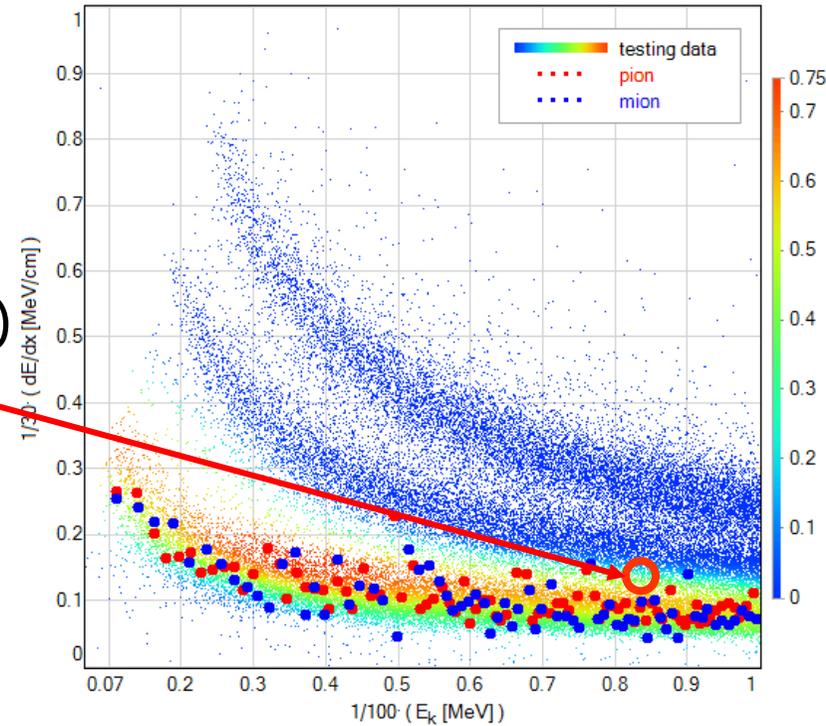

**local** squared distance to hits

**local** angle penalty term

segment number  $k$  exceeds given ratio  $c = k/n$   
 track hits number: longer tracks usually are more straight

# Neural Network particle identification

- P.id based on:
  - ↗ distance between nearby 3D hits:  $dx$
  - ↗ 3D hits and charge deposition :  $dE/dx$
- classify single  $i^{\text{th}}$  point on the track  
 $\mathbf{p}_i: [E_k, dE/dx] \rightarrow \mathbf{nn}_i: [P(p), P(K), P(\pi), P(\mu)]$
- Average  $M$  output vectors for the points  
 $\mathbf{NN} = S(\mathbf{nn}_i)/M$
- Identify track as particle corresponding to  $\max(\mathbf{NN})$
- Energy reconstruction with simulation for quenching

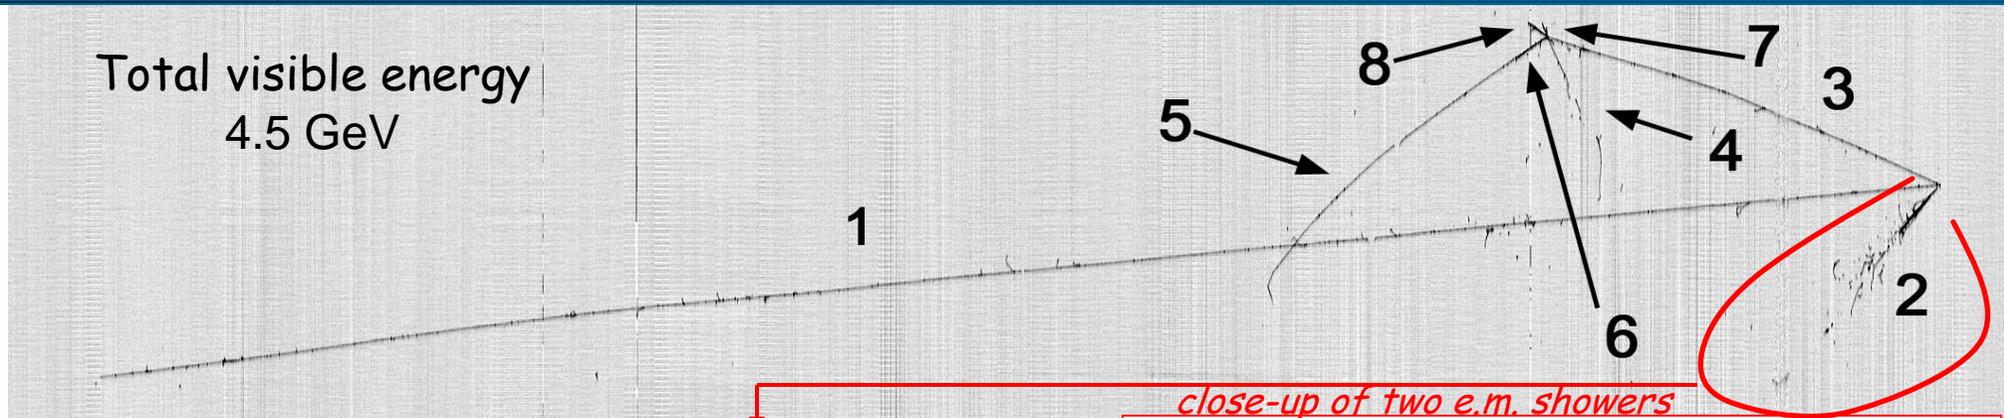

pid		<b>P</b>	<b>K</b>	$\pi$	$\mu$	efficiency [%]	purity [%]
MC							
<b>P</b>		<b>481</b>	4	0	0	99.2	98.0
<b>K</b>		10	<b>380</b>	0	0	97.4	99.0

# 2011-2012 CNGS run: physics perspectives

□ 2011-2012 run: expected  $10^{20}$  pot.

□ For  $1.1 \cdot 10^{20}$  pot: 3000 beam related  $\nu_\mu$  CC events expected

7  $\nu_e$  CC intrinsic beam associated events with visible energy  $< 20$  GeV.

Background

- At the effective neutrino energy of 20 GeV and  $\Delta m^2 = 2.5 \cdot 10^{-3} \text{ eV}^2$ ,  $P(\nu_\mu \rightarrow \nu_\tau) = 1.4\%$
- 17 raw CNGS beam-related  $\nu_\tau$  CC events expected
- $P(\tau \rightarrow e\nu\nu) = 18\% \Rightarrow 3$  electron deep inelastic events with visible energy  $< 20$  GeV.

Signal

□  $\tau \rightarrow e\nu\nu$  events characterized by momentum unbalance (because of  $2\nu$  emission) and relatively low electron momentum. Selection criteria suggest a sufficiently clean separation with kinematic cuts and efficiency  $\sim 50\%$ , allowing to detect 1-2  $\nu_\tau$  CNGS events expected in ICARUS T600 in next 2 years.

# After 2012: LAr -TPC experiment at CERN-PS

- The direct, unambiguous measurement of an oscillation pattern requires necessarily the (simultaneous) observation at several different distances. It is only in this way that the values of  $\Delta m^2$  and of  $\sin^2(2\theta)$  can be separately identified.
- The present proposal at the CERN-PS introduces important new features, *which should allow a definitive clarification of the above described "anomalies"*:
  - "Imaging" detector capable to identify unambiguously all reaction channels with a "Gargamelle class" LAr-TPC
  - L/E oscillation paths lengths to ensure appropriate matching to the  $\Delta m^2$  window for the expected anomalies.
  - Interchangeable  $\nu$  and anti- $\nu$  focussed beams
  - Very high rates due to large masses, in order to record relevant effects at the % level ( $>10^6 \nu\mu, \approx 10^4 \nu e$ )
  - Both initial  $\nu e$  and  $\nu\mu$  components cleanly identified.

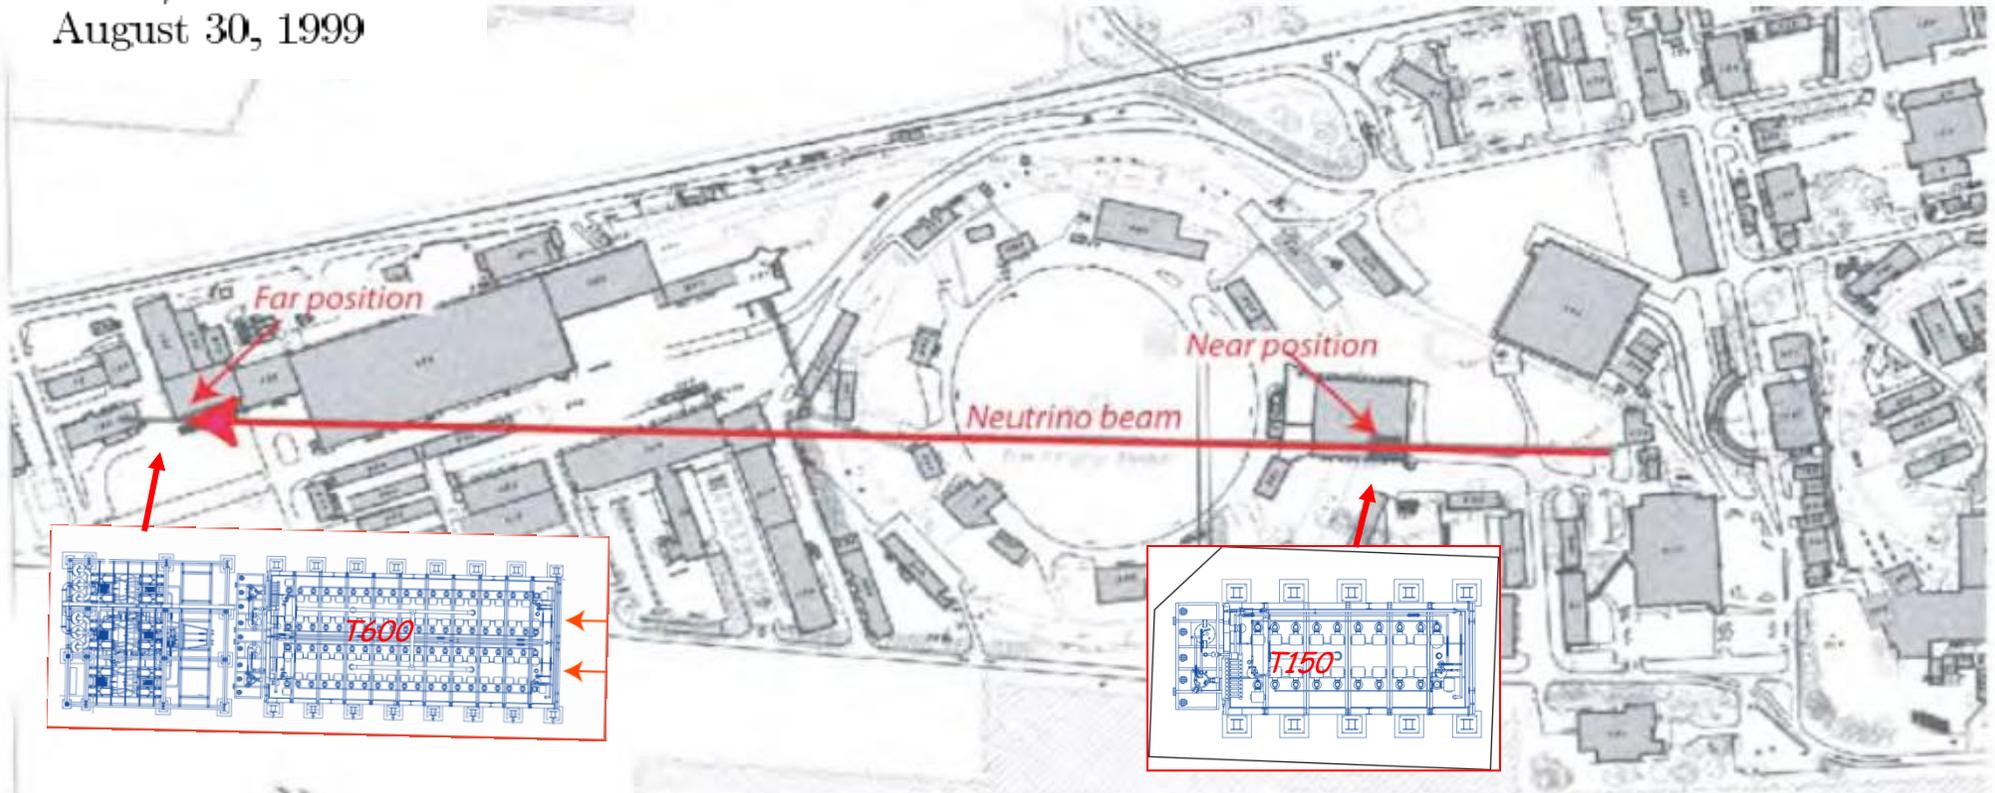

# Basic features of the proposed experiment

- Our proposed experiment, collecting a large amount of data both with neutrino and antineutrino focussing, may be able to give a likely definitive answer to the 4 following queries:
  - the LSND/+MiniBooNe both antineutrino and neutrino  $\nu_{\mu} \rightarrow \nu_e$  oscillation anomalies;
  - The Gallex + Reactor oscillatory disappearance of the initial  $\nu_e$  signal, both for neutrino and antineutrinos
  - an oscillatory disappearance maybe present in the  $\nu_e - \mu$  signal, so far unknown.
  - Accurate comparison between neutrino and antineutrino related oscillatory anomalies, maybe due to CPT violation.
- In absence of these "anomalies", the signals of the detectors at different distances should be a precise copy of each other for all experimental signatures and without any need of Monte Carlo comparisons.

# Two LAr-TPC detectors at the CERN-PS neutrino beam

CERN-SPSC/99-26  
SPSC/P311  
August 30, 1999

SEARCH FOR  $\nu_\mu \rightarrow \nu_e$  OSCILLATION  
AT THE CERN PS

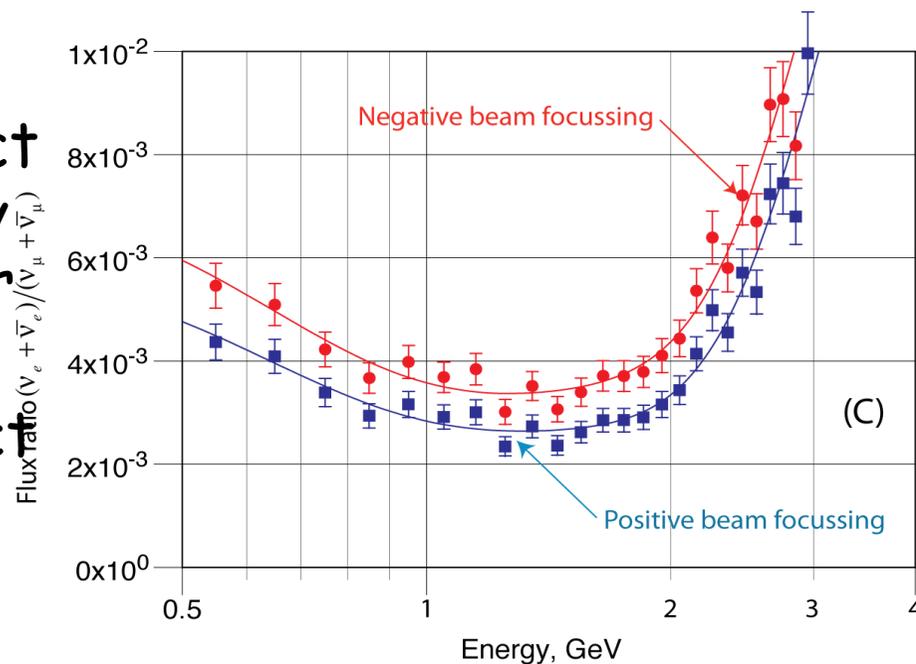

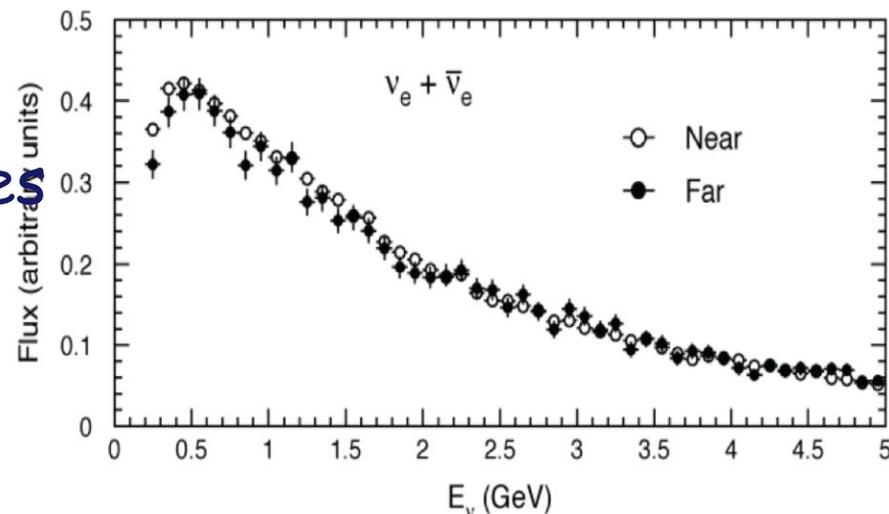

Two positions are foreseen for the detection of the neutrinos  
The far (ICARUS-T600) location at 850 m from the target:  $L/E \sim 1 \text{ km/GeV}$ ;  
The additional detector and new location at a distance of 127 m from the target:  $L/E \sim 0.15 \text{ km/GeV}$

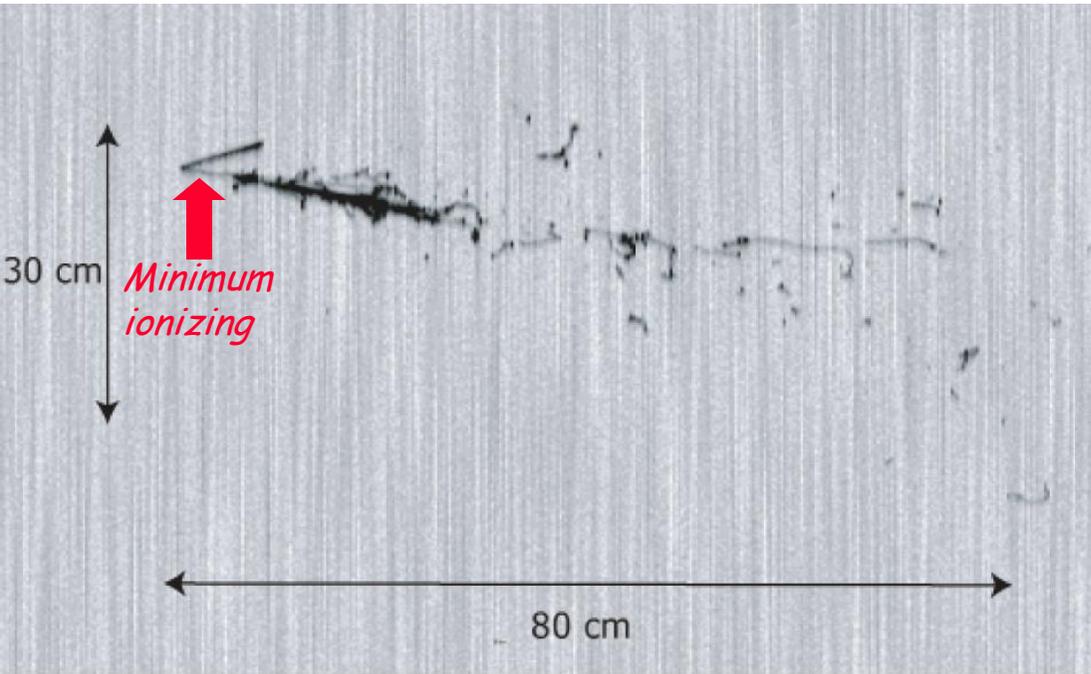

# The CERN-PS neutrino and antineutrino e-beams

Present proposal at the CERN-PS is based on the search for spectral differences of e-like specific signatures in two identical detectors but at the "Far" and the "Near" locations

- The  $\nu_e$  spectra are expected very closely identical in the "Near" and "Far" positions.
- This specific property of the electron neutrino is due to the fact that they are produced essentially by the K-decays with a much wider angular distribution.
- The effect is enhanced by the fact that both detectors have been designed with identical experimental configurations

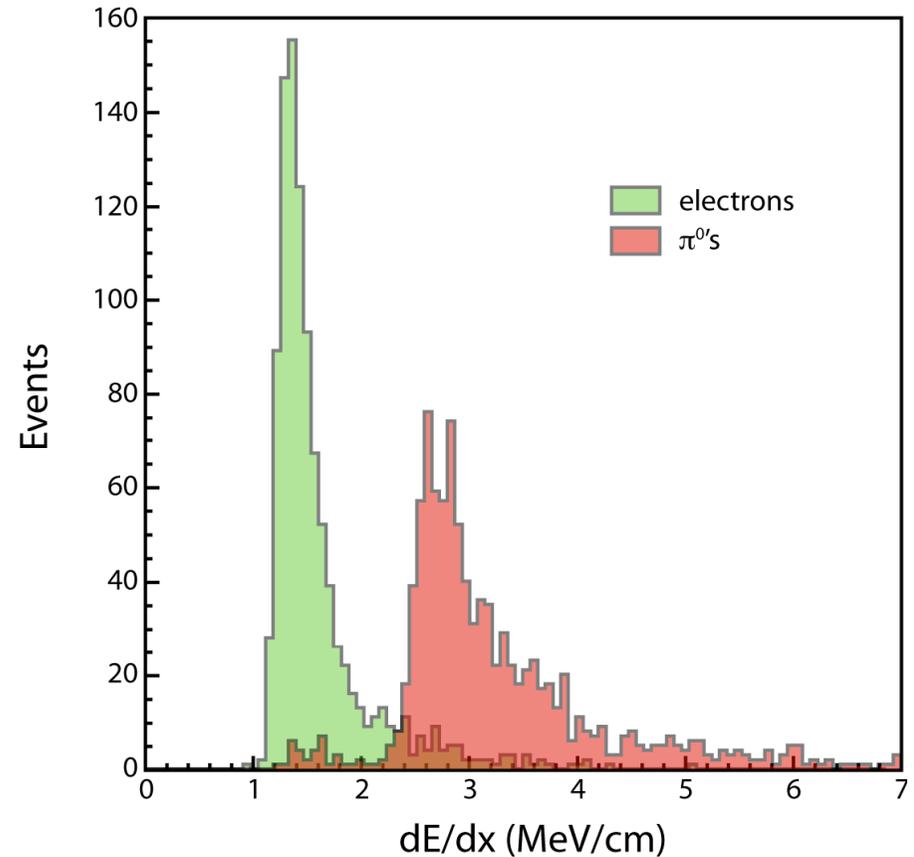

# Quasi elastic $\nu_e$ events

Collection view of a 1.5 GeV QE  $\nu_e$  event. Note the presence of a singly ionizing electron immediately after the event

In spite of the much smaller  $\nu_e$  yield (0.5% of  $\nu_\mu$ ) the extremely high sensitivity for the electron signature ensures an excellent detection efficiency

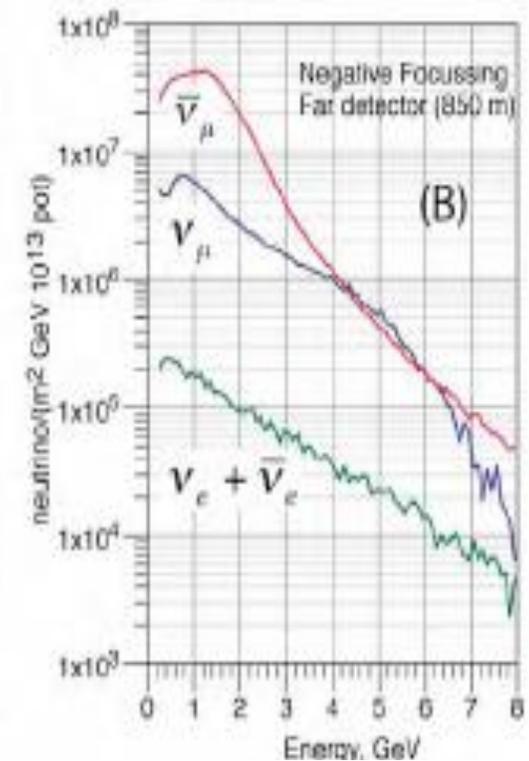

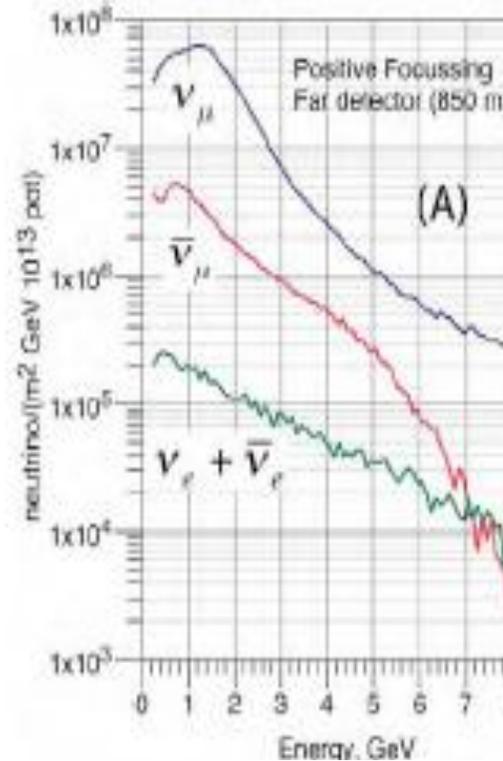

Electron- $\pi^0$  separation obtained in the LAr-TPC using ionization measurements along tracks in the vertex region

# Expected CERN PS neutrino beam spectra

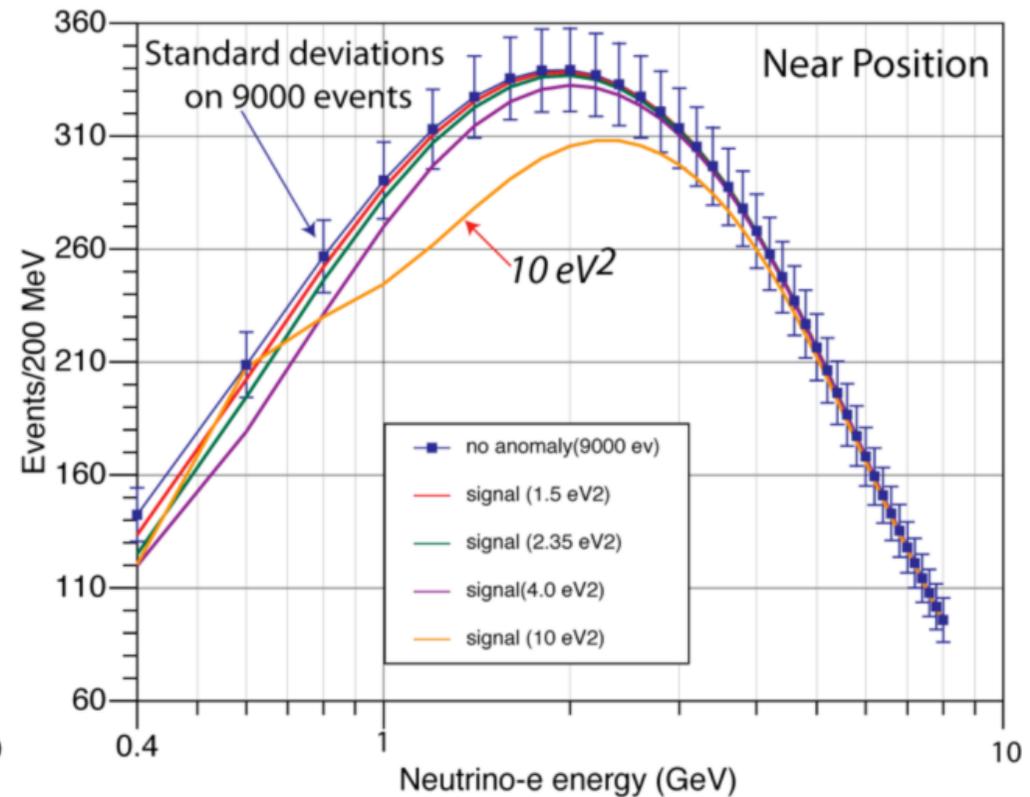

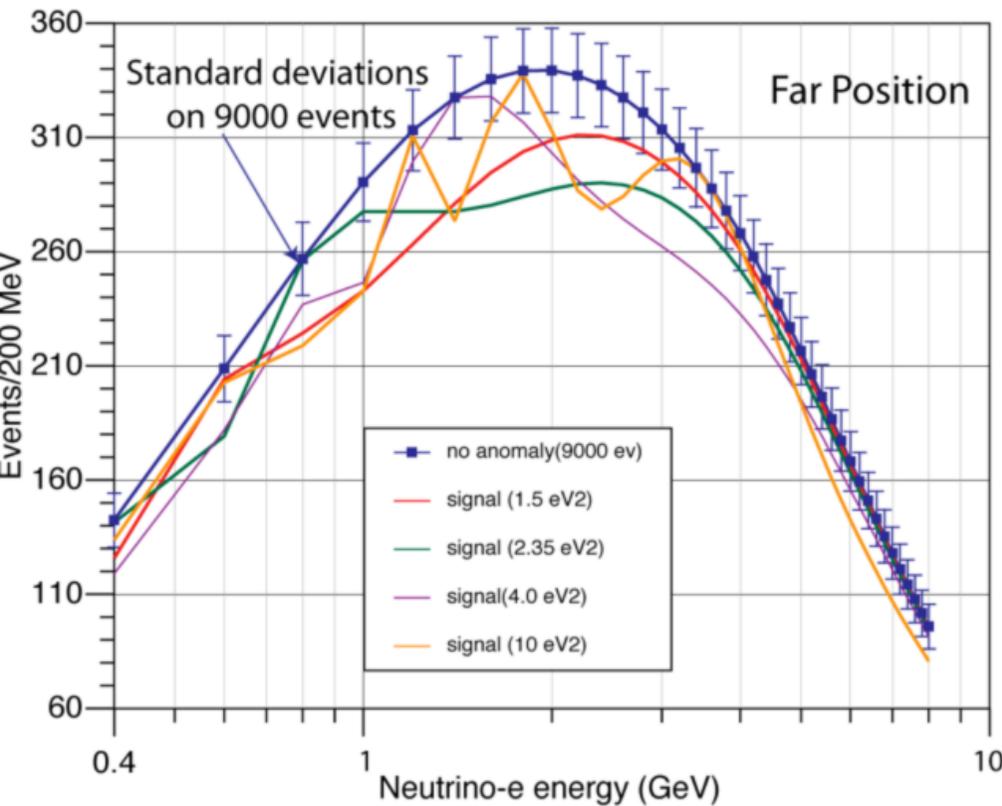

2 year PS neutrino beam T600 + T150 exposure for both neutrino (A) /antineutrino (B) mode with positive/negative meson focusing for different pot intensity:

- $2.5 \cdot 10^{20}$  pot - basic old "I216" option corresponding to only 30 kW beam power
- $7.5 \cdot 10^{20}$  pot - upgraded PS option (90 kW)

	$\nu$ focus		$\bar{\nu}$ focus	
	FAR	NEAR	FAR	NEAR
Fiducial mass	500 t	150 t	500 t	150 t
Distance from target	850 m	127 m	850 m	127 m
$\nu_\mu$ interactions (or $\bar{\nu}_\mu$ for $\nu$ focus)	3.600E+6	5.400E+7	6.000E+5	6.900E+6
QE $\nu_\mu$ (or $\bar{\nu}_\mu$ ) interactions	1.350E+6	1.980E+7	2.610E+5	3.000E+6
Events/Burst	0.510	7.500	0.090	0.900
Intrinsic $\nu_e + \bar{\nu}_e$ from beam	27000	360000	6000	87000

# Sensitivity to $\nu_e$ (and $\nu_\mu$ ) disappearance signals

The energy distributions of the electron neutrino events is shown in (a) and (b) respectively for the "Far" and "Near" and a number of possible values in the region of  $\Delta m^2 > 1\text{eV}^2$  and  $\sin^2(2\theta) \approx 0.16$  for 9000 neutrino events. If confirmed without any doubt such a large mass difference will have an important role in the explanation of the existence of the Dark Mass in the Universe.

# Sensitivity to disappearance anomalies

- Sensitivities (90% CL) in the  $\sin^2(2\theta_{\text{new}})$  vs.  $\Delta m_{\text{new}}^2$  for an integrated intensity of (a) at the 30 kWatt beam intensity of the previous CERN/PS experiments, (b) the newly planned 90 kWatt neutrino beam and (c) a 270 kWatt curve. They are compared (in red) with the “anomalies” of the reactor + Gallex and Sage experiments. A 1% overall and 3% bin-to-bin systematic uncertainty is included (for 100 MeV bins).

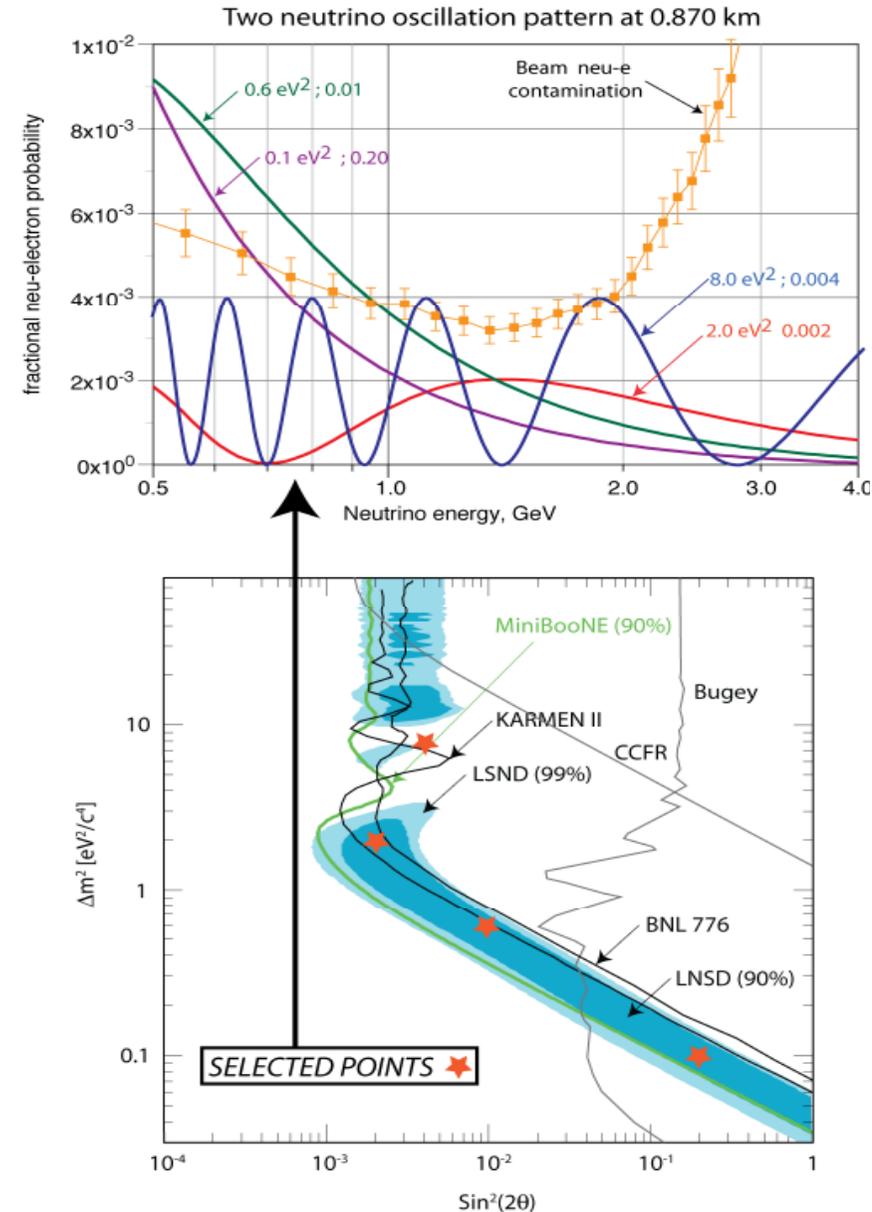

# Expected signal for LSND/MiniBooNE anomalies

- Event rates for the near and far detectors given for  $7.5 \cdot 10^{20}$  pot for  $E_\nu < 8 \text{ GeV}$  (90 kW beam power). The oscillated signals are clustered below 3 GeV of visible energy.

	$\nu$ focus		$\bar{\nu}$ focus	
	FAR	NEAR	FAR	NEAR
Fiducial mass	500 t	150 t	500 t	150 t
Distance from target	850 m	127 m	850 m	127 m
$\nu_\mu$ interactions (or $\bar{\nu}_\mu$ for $\bar{\nu}$ focus)	3.600E+6	5.400E+7	6.000E+5	6.900E+6
QE $\nu_\mu$ (or $\bar{\nu}_\mu$ ) interactions	1.350E+6	1.980E+7	2.610E+5	3.000E+6
Events/Burst	0.510	7.500	0.090	0.900
Intrinsic $\nu_e + \bar{\nu}_e$ from beam	27000	360000	6000	87000
Intrinsic $\nu_e + \bar{\nu}_e$ ( $E_\nu < 3 \text{ GeV}$ )	11700	162000	2640	39000
$\nu_e$ oscillations:				
$\Delta m^2 = 2. \text{ eV}^2; \sin^2 2\theta = 0.002$	3582	3150	690	174
$\Delta m^2 = 0.4 \text{ eV}^2; \sin^2 2\theta = 0.02$	6249	7020	990	345
$\Delta m^2 = 0.064 \text{ eV}^2; \sin^2 2\theta = 0.96$	10050	3750	1395	420
$\Delta m^2 = 4.42 \text{ eV}^2; \sin^2 2\theta = 0.0066$	8940	75150	1470	9660

# Determination $\Delta m^2$ and $\sin^2 2\theta$ values in $\nu_\mu \rightarrow \nu_e$ anomaly

- It appears that the present proposal, unlike LNSD and MiniBooNE, can determine both the mass difference and the value of the mixing angle.
- Very different and clearly distinguishable patterns are possible depending on the values in the  $(\Delta m^2 - \sin^2 2\theta)$  plane.
- The intrinsic  $\nu_e$  background due to the beam contamination is also shown.
- The magnitude of the LNSD expected oscillatory behavior, for the moment completely unknown, is in all circumstances well above the backgrounds, also considering the very high statistical impact and the high resolution of the experimental measurement.

# Comparing LSND sensitivities (*arXiv:0909.0355*)

Expected sensitivity for the proposed experiment exposed at the CERN-PS neutrino beam (left) for **2.5 10<sup>20</sup> pot (30 kW basic option)** and twice as much for anti-neutrino (right). The LSND allowed region is fully explored both for neutrinos. The expectations from one year of at LNGS are also shown.

Thank you !
